Sorry for such a basic question, but this is all new and exciting technology...
I'd like to try breadboarding another power supply with a type 80 rectifier. I buzzed out a nameless transformer and have identified a ~600VCT with filament outputs of 7.1, 7.1, and 5.5 volts. These are measured open circuit with 120V input. There are no center taps on the filament outputs and they are isolated from one another and the HV.
I see the type 80 wants 5V to light the filament. Is the 5.5V winding really a "5 volt" winding and its anticipating some voltage drop when its drawing two amps current? How close do these filament voltages need to be in practice? I can always drop the voltage with a power resistor if I need to, but simpler is better.
Thanks,Andy K0SM/2

Hi Andy,

The voltage you are measuring could be high for 2 reasons (1) there is no load on the windings when you are doing your voltage measurement, and (2) your line voltage may be higher than what was normal back when the transformer was manufactured. I'd be willing to bet the 5.5V winding is nominally 5V, and the two 7.1 vollt windings are nominally 6.3V. Hook up the 80 filament to the "5.5V" winding, take a measurement, and see what you get. I generally consider anything within 5% of the target filament or heater voltage acceptable.

If the voltage is still too high you can try using one or both "7.1V" windings in series-aiding to buck the primary voltage (in series-bucking, of course). All this means is that you get the phase of the filament winding correct wrt the primary winding.

Thanks Larry.
I wired it up and I'm getting expected B+ DC on the cheap-o digital meter sans filter, so that's good. It's still 5.3V or so, but probably good enough. Now to see if I can find a choke....

Did somebody say large tubes!!!!!!!!!!!:>) I love large tubes.
Nice setup. Should do the photo in black and white just for fun and see how it looks.
I have a parasitic on my 45 TNT. I had it tuned up on 7290 today just to make sure it still works. I don;t use it much on CW anymore. I added a parasitic to my No 19 WS PA tube as well. I don't think you can go wrong putting one in the circuit for all the time it takes.
It is interesting about different tubes. My rat trap works wonderful on a 201A but is stubborn and not much fun on a 45 although I did run the after midnite BK with it. I decided to leave it a 201A afterwards because it works so well with it. I think that is why I like the 211 too. It seems to me to be an easy tube to work with for me. Never had a 10 or a 27.
I still got to work you Matt. The Recording I sent today if you got it , you come on a bit before the halfway point but it is pretty good. Love your mic! Where did you ever find that?

Thanks Larry. It's coming along.

Yes, big tubes. Hopefully. Right now I have two 203A's with the old brown sockets. If I get a power supply up to snuff I'd like to play with some 852's. Probably not very efficient but they look cool. I have a huge cardwell split section that wants to be in a push pull amplifier. Which, BTW, if anyone has an old 3/8 shaft lever/dial they want to get rid of I'd be interested. That said, I am still very interested in the low power work. I have an ancient uv-201-A I'd like to put into low power work. Might have to find a 199.

The mic was an ebay find. Its that Western Electric T-12. 232BW carbon element. Im watching one now that has the scissor boom attached, which would be great for loop work. Still playing with the loop, trying to figure out if the mic is actually doing its job. The empty space on the desk is left for a modulator anyway.

Black and white pics, because I was thinking the same thing. Thats me taking a quick 1920s ham selfie.

When you put your mic on an ohm meter and speak what happens?
When you connect a flashlight bulb or pilot lamp across your loop without the mic what happens? Has to be single button mic. Double button mics are not suitsble.
You have to find the balance. Have enough absorption to produce a reasonable level of modulation but not enough to bother the Tx itself. It is easy to have too much. I had the 45 TNT going yesterday on the upper end of 40M on phone. Still works pretty good. Will never forget my first Loop QSO with Ve6PG (the other Tim Smith.)
I have several 201A rigs. 201A is probably my favourite tube. For the BK the last two years I would say 90% of my work was with those 201A rigs. Very tuf tube able to take a lot of abuse and run at much higher voltages.

No hands, Use only on moderate power rigs, Consistant coupling and no more then required. All adds up to a usable system for light duty use.

This is my 201A rig I used this years BK on 80M so many of U have done a CW QSO with it. The vintage telephone carbon mic is bolted to the mod base and I speak through a tube. This eliminatethe biggest problem. Hand capacity, wiggling wires etc. I am quite happy with it. It is tuned up on 3610 which is about as high as this TX can go.

I really enjoy running this rig normally (CW) as well. It seems to do ok. I find myself dragging it out every wUek or so for some fun.

So how do you know how much coupling to use? First get it close enough you can hear yourself well (deep rich) in a monitor receiver. Tuned in right on. Then turn on the receivers BFO and try speaking again (or switch to CW on the rx)
Speak again at the same level. While the strength may change as you speak the Note (ie 600 cycles) should not. Get as close a coupling as you can with this stability still there. This little rat trap does this easily so it is possible. No warbling. No freq change. If it did the tone would change. It doesn't when you get the coupling right.

12953. 27 transmitting specs

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-15 18:02:20 UTC
From: JAMES HANLON
Topic: 12953 Message: 12953

The following specs for the '27 in General Purpose Receiving service comes from page 88 of the 1931 ARRL Handbook.

Output, 0.165watts
Plate Voltage 180
Plate Current 5 ma.
Suggest Grid bias -13.5 volts
Filament 2.5 vac, 1.75 amps
Amplification Factor (mu) 9
Plate Impedance 9000 ohms
Mutual Conductance 1000 micromhos

Neither the TNT nor the Hartley self-controlled oscillators shown in this Handbook mention using a '27. The TNT is "designed to use a Type '10 tube with a 500-volt d.c. plate supply and a 7.5-volt a.c. filament supply, or a type '01-A tube with a 135-volt d.c. plate supply and a 6-volt d.c. filament supply." However, the '01-A is also rated for General Purpose Receiving service and carries a Plate Voltage rating of 135 volts (at 3 ma.) (mu 8, Rp 10,000, Eg -9 v). So I suspect that the Handbook folks would not have exceeded 180 volts if they ran a '27 in one of these oscillators.

In the 1935 Handbook the 27 is rated with "Standard Receiving Tubes" as follows.

Description: Triode, Detector, Amplifier
Filament 2.5 volts, 1.75 amps
Plate Voltage 250
Negative Grid Volts 21
Plate Current 5.2 ma.
Plate Resistance 9250 Ohms
Mutual Conductance 975 Micromhos
Amplification Factor (mu) 9.0

In this Handbook the single-tube Hartley is no longer shown. The single tube TNT is there, and the tubes recommended for it are a 10 with a 500 volt plate supply, a 45 with a 350 volt plate supply, and a 01-A with a 135 volt plate supply.

Tnx a lot Jim, for the 227 tube info. It will come in real handy when
and if I get around to trying one. Seems the '27 may be a bit of a 'sleeper'
as far as its use by our BKers. Altho, I believe I have worked several so
it may be used more than I think. Seems ideal for the beginner and seasoned
BK op. And good for us, maybe a bit low powered for the audio amp guys....
so far at least.

I'm trying to find a article I remember seeing, probably from the 50s or maybe early 60s. So far my search of the QST archives hasn't helped but maybe one of you recall the article/source.

Basically the article was a tube transmitter construction article but it started with discussing front panel and chassis layout/design options. Some of the possibilities the article recommended as better than others and explained why.

This sound familiar to anyone?

12959. Re: [AWA Group] 27 transmitting specs

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-16 12:40:41 UTC
From: Louis Vermond
Topic: 12953 Message: 12959

Thank you for this posting, Jim. 73, Lou

The following specs for the '27 in General Purpose Receiving service comes from page 88 of the 1931 ARRL Handbook.

Output, 0.165watts
Plate Voltage 180
Plate Current 5 ma.
Suggest Grid bias -13.5 volts
Filament 2.5 vac, 1.75 amps
Amplification Factor (mu) 9
Plate Impedance 9000 ohms
Mutual Conductance 1000 micromhos

Neither the TNT nor the Hartley self-controlled oscillators shown in this Handbook mention using a '27. The TNT is "designed to use a Type '10 tube with a 500-volt d.c. plate supply and a 7.5-volt a.c. filament supply, or a type '01-A tube with a 135-volt d.c. plate supply and a 6-volt d.c. filament supply." However, the '01-A is also rated for General Purpose Receiving service and carries a Plate Voltage rating of 135 volts (at 3 ma.) (mu 8, Rp 10,000, Eg -9 v). So I suspect that the Handbook folks would not have exceeded 180 volts if they ran a '27 in one of these oscillators.

In the 1935 Handbook the 27 is rated with "Standard Receiving Tubes" as follows.

Description: Triode, Detector, Amplifier
Filament 2.5 volts, 1.75 amps
Plate Voltage 250
Negative Grid Volts 21
Plate Current 5.2 ma.
Plate Resistance 9250 Ohms
Mutual Conductance 975 Micromhos
Amplification Factor (mu) 9.0

In this Handbook the single-tube Hartley is no longer shown. The single tube TNT is there, and the tubes recommended for it are a 10 with a 500 volt plate supply, a 45 with a 350 volt plate supply, and a 01-A with a 135 volt plate supply.

12968. Crystal Etching

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-18 17:08:54 UTC
From: JAMES HANLON
Topic: 12968 Message: 12968

There's been a bit of discussion on the list recently about crystal grinding, so when I ran across an article about Crystal Etching this morning I thought I would pass it along.

The article is, "A Safe Method for Etching Crystals" by Albert J. Newland, W2IHW. It originally appeared in QST, January 1958, and it was republished in the ARRL book, Single Sideband for the Radio Amateur, pp 52-53. Newland describes using an ammonium bifluoride solution to etch FT-243 type crystals. His particular solution is reported to move a crystal (of unspecified original frequency) about 100 kc in 10 hours of etching. One hour of etching moves the crystal about 25 kc.

If you are interested in the article I'll gladly scan it and forward it to you.

SO I am rethinking a couple of things. One is my tube choice. I prefer the 201A tubes and that is fine as they work well in the BK on the low power times and I feel I give little if anything away. I have quite a few but dont pass up too many chances to improve that stockpile. When I step up one I use 45s. Probably because my brother gave me a handful of them many years ago and one turned out to be Ok. I used it for awhile . In fact it died one night when I was tuning up for a sched with Lou. I got a replacement from Lou and it was and still is good. I have since got two more. One is IFFY and one is a when you're desperate tube. I used to be able to buy them new but no more. They seem to lose their punch after a while (201As don't care. They are the Timex of tubes. Take a licking and keep on ticking) Now 45s are way up in price compared to even a year ago. No 10s seem to be popular with many of you so I want to know. Are they robust like a 201A or are they touchy like a 45 (171As are also iffy sometimes) Has anyone had a bum 10 or had a recent failure ? I wanna know before I part with some gold.

Don, I am also a believer in the robustness of the '01As. My first BK rig was the '29 TNT. Even then, abt 15 yrs ago, I didn't like the prices of the '10s, so went to the '01A (wish I'd bought a few '10s back then). I was real skittish abt the B+ so for the first yr or two kept it at about 180vdc or so. Now I run the TNT at probably 250 and also use an '01A in the 160m 1924 Meissner ckt and at a bit over 300vdc. I have read in the old QSTs that much higher B+ values was used on the '01As. So far have not blown an '01A (or a '10). So, I am a firm believer that the '01As are tuff little tubes and should be used more for our BK rigs.

Also, I assume in your quest for the '10, you are also including the VT-25...which is a '10 in modern dress (ST style).....GL, 73 de Bill K4JYS

Yes Bill. I knew you were also a 201A fella. I read once where a guy claimed he had a 1000 volts on one. I would be nervous there but run mine at 282v keydown all the time.I guess I wouldn't whimp out even at 420v or so.
I have been looking at building a push pull self rectified one. I have an article form 1930 detailing why that works and how to do it. it claims it should be indistinguishable from a filtered DC supply if done as they say and should have no trouble falling in line with the new 1929 rules.
I could use the newer militatry version of the 10 but it just doesnt look right. some of my 45s are that style do. Doesn't seem right. But my gut feeling follows your opinion exactly.

Does anyone have any experience with the older brass-based UV-201A's as far as their robustness and plate voltage? One thing on my punch list is to build a "1924" transmitter along the lines of what my great grandfather might have had. He's listed as having a "5W" transmitter in the 1924 callbook, which probably indicates a CW transmitter and something like a UV-201/A, but that's just speculation. I'm comfortable working with a little historical fiction, and it seems like a reasonable goal that probably doesn't have me searching for unobtainium at premium prices. The audiophile/tube-collector triangulation seems to be manageable.
As much fun as an older UV201/202 combination would be, it looks like the tungsten filaments might have short lives. Am I correct in that all the "A" suffix brass-based 201's have thoriated fillaments? How about gas problems? Since I would plan on actually using such a tube rather than having it look pretty on a shelf I'm interested in any operational experience with such old tubes.

Andy K0SM/2

Hi Andy,

I've enjoyed your new OT rig adventures.

"5W" transmitter in the 1924 callbook ... In '24 a 5W(after) rig would have a UX-202. I'm sure others here would verify this. If you would not have to skip any meals suggest that you go nuts and get one. As you may know, price out about $150-75 depending on condx etc. ...about the cost of a 210...but not as sexy. You could use the 202 for Special QSOs using a 10 or 201a the rest of the time.

U / X-201As? 300B+ would be interesting.

I don't know about the UV 201s but the 201As are as close to indestructible as a tube can be, I run them 6 volts too. most of the old neutrodynes which is where I fnd them were often run of the car battery for heaters. you gotta know that many people accidentally or uninformedly ran them at 6 volts or slightly more and never gave it a second thought. Then I found an old article on how to rejuvenitate them running them for a couple of hours at absolutely insane voltage on the heaters. Another place said to run them 8 hours at 7.5 then let hem cool and run them at normal. It was then I realized I can run them safely at "Approx 5 volts" so they have been at 6v ever since. I have yet to lose one although eventually that is inevitable. I suspect they are tungsten filaments because the 45s are thoriated and they just can't wait to die or even blow even at 2.5 volts. Very fragile tube in my experience. 201As just dont care. They work.

But you shouldn't run those high voltages on them when you have plate voltage applied, or you risk shortening the life of the tube dramatically. The rejuvenation process does risk burning out the filament, but here we're talking about a tube that is dead anyway unless we try it, so there's nothing to lose.

> It was then I realized I can run them safely at "Approx 5 volts" so
> they have been at 6v ever since.

The common practice was to use a 6V storage battery, yes, but to drop the voltage to 5V with a rheostat. The rheostat also allowed one to adjust for 5V as the batter lost its charge.

> I have yet to lose one although eventually that is inevitable. I
> suspect they are tungsten filaments because the 45s are thoriated and

UV201's are tungsten (not thoriated), UV201As are thoriated tungsten, and 45s are tungsten coated with rare-earth oxides so that they are good emitters at even lower voltages than thoriated tungsten. But they are more fragile.

> Very fragile tube in my experience. 201As just dont care. They work.
>

I haven't found 45s to be fragile as long as you keep the filaments as close as possible to 2.5V. I accidentally put 7.5V on a pair several years ago, for under a minute until I realized my error, without any plate voltage applied. It didn't burn out the filaments but after that they had no emission and wouldn't amplify. I think it "boiled" the oxide coating off the filament.

The Amateur Scientist section of Scientific American Magazine had an article years ago that used an 01A at high voltage to generate Xrays. Maybe some caution should be exercised when operating the 01A (or any other tube) at voltages higher that rated values. Some tubes emit Xrays even at rated voltages, like the HV voltage regulator in early color TV's.

UV201's are tungsten (not thoriated), UV201As are thoriated tungsten, and 45s are tungsten coated with rare-earth oxides so that they are good emitters at even lower voltages than thoriated tungsten. But they are more fragile.

Very fragile tube in my experience. 201As just dont care. They work.

I haven't found 45s to be fragile as long as you keep the filaments as close as possible to 2.5V. I accidentally put 7.5V on a pair several years ago, for under a minute until I realized my error, without any plate voltage applied. It didn't burn out the filaments but

after that they had no emission and wouldn't amplify. I think it "boiled" the oxide coating off the filament.

You know it doesn't really matter to me. Sure they were intended as a 5 volt tube. But somehow I know many were run a little hot because grandma and grandpaw couldn't see the "set to this line" printing on the meter if it had one and most didn't so it doesn't take genius to realize many if not most were run where they sounded the best. However nothing wrong with being careful.
Anyway I run them as I run them. My 45 experiences have been similar. One mistake and they become a shelf queen in a heartbeat. They are a pretty good tube when they are good but intolerant of any error. Like I said before the 201A s don't care. I guess I want to know are the 10s robust or are they easily damaged like the 45 tubes are.

Some may remember my recent UV199 experiment. It was unsuccessful using either of the two used Uv199 I was able to come up with but when I built an adapter for a 201A and popped it in I got very good reports so I know the Tx is good. I was able to score two NIB uv199 tubes for less then I paid for the duds and they have been shipped so it will be interesting to see how it pans out. I had been tempted to change the socket for a UX4 style but built the adapter instead from a dud UV199 and a 4 pin socket so it is simply a matter of installing one when it gets here. I am hoping it works. I still have my 3 volt heater supply at the ready. If it does I may be tempted to build a matching regen with the other tube.

I haven't a lot of experience with 10s.

But FWIW they have a thoriated-tungsten filament (I'm not sure about
some of the earliest UV-210s, which MIGHT be just tungsten).

Don,

The 210 and the 45 each has strengths and weaknesses.
The 210 is more durable electrically - if you damage the emissive layer, (for example, by drawing as much current than the filament can emit) the filament can be rejuvenated just like the 01A. Thoriated tungsten filaments are more tolerant of high plate voltages compared to the oxide coated filament of the 45..
The 45 has a heavy ribbon filament that is mechanically much stronger than the thin brittle filament of the 210. The death of a 45 will most often be the filament losing its emissive ability, while the death of the 210 will likely be the filament opening, just like the 01A.

In my experience, the 45 is long-lived. I put a pair of well used globe 45 tubes in an audiophool amplifier. After about 2000 hrs of additional use, they still work fine. But they were subjected to filament voltages within spec and a conservative plate voltage.

Don,

I've had good experience with the '10. I run a UX-210 in my Hartley and a pair of VT-25 10Ys in my MOPA. I run around 300 volts, regulated, on the oscillators and 480 volts on the amplifier in my MOPA. I keep the filaments at 7.5 vac. They all give good service without complaint. I did have one VT-25 that was gassy when I got it, but what can you do... Harold, KB0ROB, gave me the 10Ys and I helped him with coils for his SW-3, a nice trade.

There's one thing you might want to do if you are concerned about a precious '10. Get an 801, which is early 30s vintage and just a more rugged version of the '10 intended for transmitter service, and use it for tune up, experimentation, and day-to-day service. Reserve the '10 for contest work where you need its 1929 vintage authenticity. An 801 is usually available for a lot less than a '10.

Thanks everyone for the info. Now just for the record I don't want anyone to think I dont watch heater most voltages very carefully. It is just that I know the 201A doesn't care and actually likes the high side of between 5 and 6 with no loss of reliability and since it is easy do, I do. My 45s I am very careful with because they are easily damaged. I have three. One is very good and one ok. and one that is useless. I look at the10 specs often and really don't see any huge advantage over the 45. However if it was more robust I might be moved. For now I think I will just stay put. I have more old style rigs then fingers so I should settle down perhaps. They are just so much fun and easy to build. The 801 is an interesting idea.

Hi Jim et all,Perhaps this price list isn't typical, but FWIW, ESRC lists 801s at $75, vs $70 for the type 10. (Both well beyond my very flat pocketbook! --- Thus, I will continue to use my pre-owned and pre-used 27's!---less than $1 each at a long ago, but not forgotten Ten-Tec hamfest). Coincidently, there was mention of using a triode connected 6L6 (low mu connection--screen grid connected to plate), as a replacement for the 801, in a recent posting on the Glowbug list. 73 de ron n4gjv

Hi Andy,
I haven't used the brass base '01A but I am using a C-301A which is from around 1924 in a HB Meissner osc from a 1924 QST article. Its a bit of an odd circuit, but I finally got it going and use it on 160mtrs. I am getting a couple of watts output into a 160m coax fed inv L. I run around 325vdc for B+. Have worked from FL up into VE3. As, think it was, Lou mentioned, the '5 watter' was probably a 202. I have a couple of 202s, with good fils., but haven't been able to get them to oscillate. Boy, they are a real light show....fils. very bright. May just stick with the C-301A. Having plenty of fun with it.

Subject: Re: [AWA Group] Favourite tube

Does anyone have any experience with the older brass-based UV-201A's as far as their robustness and plate voltage? One thing on my punch list is to build a "1924" transmitter along the lines of what my great grandfather might have had. He's listed as having a "5W" transmitter in the 1924 callbook, which probably indicates a CW transmitter and something like a UV-201/A, but that's just speculation. I'm comfortable working with a little historical fiction, and it seems like a reasonable goal that probably doesn't have me searching for unobtainium at premium prices. The audiophile/tube-collector triangulation seems to be manageable.

As much fun as an older UV201/202 combination would be, it looks like the tungsten filaments might have short lives. Am I correct in that all the "A" suffix brass-based 201's have thoriated fillaments? How about gas problems? Since I would plan on actually using such a tube rather than having it look pretty on a shelf I'm interested in any operational experience with such old tubes.

Andy K0SM/2

Don, I am also a believer in the robustness of the '01As. My first BK rig was the '29 TNT. Even then, abt 15 yrs ago, I didn't like the prices of the '10s, so went to the '01A (wish I'd bought a few '10s back then). I was real skittish abt the B+ so for the first yr or two kept it at about 180vdc or so. Now I run the TNT at probably 250 and also use an '01A in the 160m 1924 Meissner ckt and at a bit over 300vdc. I have read in the old QSTs that much higher B+ values was used on the '01As. So far have not blown an '01A (or a '10). So, I am a firm believer that the '01As are tuff little tubes and should be used more for our BK rigs.

Also, I assume in your quest for the '10, you are also including the VT-25...which is a '10 in modern dress (ST style)......GL, 73 de Bill K4JYS

Subject: [AWA Group] Favourite tube

SO I am rethinking a couple of things. One is my tube choice. I prefer the 201A tubes and that is fine as they work well in the BK on the low power times and I feel I give little if anything away. I have quite a few but dont pass up too many chances to improve that stockpile. When I step up one I use 45s. Probably because my brother gave me a handful of them many years ago and one turned out to be Ok. I used it for awhile . In fact it died one night when I was tuning up for a sched with Lou. I got a replacement from Lou and it was and still is good. I have since got two more. One is IFFY and one is a when you're desperate tube. I used to be able to buy them new but no more. They seem to lose their punch after a while (201As don't care. They are the Timex of tubes. Take a licking and keep on ticking) Now 45s are way up in price compared to even a year ago. No 10s seem to be popular with many of you so I want to know. Are they robust like a 201A or are they touchy like a 45 (171As are also iffy sometimes) Has anyone had a bum 10 or had a recent failure ? I wanna know before I part with some gold.

The 10 can take higher plate voltages and run safely as higher power than the 45. But within a 45's plate voltage rating, you'll actually get more power out of a 45 than a 10 under those conditions.

Yes, I have no complaints on the 45s output. I guess I have one transmitter that only real good ones work in although any 201A works there. Deep in my head I think I don't like that all my good 45s are ST instead of Balloons. I thought about a easy high power tube for some of the rigs to sub in when not BK ing. You know a 811A fits and with a cap and a clip lead for $37.95 is a quick fix. But now with the two 211 rigs it is kind pointless to bother. Besides it isnt power that is the problem. It is getting an answer. You may be able to ring the bell on the RBN or the SDR Mich remote but if one of us is not listening we often don't get reply except from the curious or the senior hams who still remember that wonderful sound. That is why co-operate testing like we did that Sat is so good. We got the job done easily and quickly and then we all had some fun too. Any day you can help a pal out and have fun as well is a good day.

There is an 801A on ebay now. As of 3/22/2015, 10:54 a.m. it will be available for another 5 days, 7 hours. It's current price is $0.99 plus $6.28 shipping. The title of the listing is "1 vintage Hytron VT-62 801A tube-tested- 10Y". The category breakdown of the listing is Consumer Electronics/Vintage Electronics/Vintage Audio & Video/ Vintage Parts & Accessories/Vintage Tubes & Tubes Sockets.

Hi Don,
The version I built was the four coil configuration. The tank coil is split in half and each half is at right angles to each other to reduce coupling. The grid coil goes into one half of the tank coil and is rota-table. A plate coil goes into the other half of the tank coil and is moveable. These smaller coils can be adjusted for coupling. The only 'connection' the tank coil has back to the plate and grid is thru the small coupling coils. The tank coil is 1/4" copper tubing and around 5" or so in dia. I added a coupling coil at the bottom end of the tank coil...6-8 turns of #12 copper wire, I think it is, so I can couple to the coax fed 160m inv. L. Also have a var. cond. there for antenna tuning. If interested, I can send along a pix or two and can also scan the article if needed.....July 1924 QST, pg 49. Another config. is the three coil version. Another article was in May 1924 QST...pg 18. From what I read, the 4-coil version is the better of the two. Like most of these rigs, anything ya adjust will move the freq. But I have found on this one, that once set up, the freq is very stable...no drift. However, most any amount of antenna/feedline movement will cause that beautiful 'wind modulation'. I am using a pair of CX-316Bs as rectifiers with no filter choke....just condensers and a bleeder...note is good, and very little chirp.
Those rectifiers light up like '02s...and are much bigger & brighter than the lil '01A... sorta gives me a chuckle when I compare the sizes.

This was sorta of a hodge-podge explanation so if ya need any more info, let me know.

Bill, I am curious about the Meissner. It is my understnding the tank LC is in the plate circuit and the tickler in the grid circuit but that may be just rumour. Is that so or is your circuit something different?

Here ya go Don.
As you can see, its a rats nest. But this project has been going on for several years.... for no other reason than its working and I'm lazy. I do intend to rebuild it for a better look, but who knows when....hi. The pix were taken before I made the p/s....using a Heath bench supply here. The little 'chassis' on the left is for fil. adjustment which I run at 5vac. And, yes, I used this rig in the BK on 160m. It did take a while to get things running on the right freq. I had to add a turn or two to the tank coil halves, but the coupling coils I left as suggested in the article. If it ever gets out of adjustment,
it takes a while to get the tuning condensers back to the sweet spot for freq. and pwr output. Also, I have found on this one, that if the plate current gets to 20ma or more the note gets ruff, so I can usually find a sweet spot at a lower current that gives a good note and pwr out. I think the last time I ran it, I was able to get about 2 watts out.

WOW! A lot of time and effort has gone into that! , Pretty impressive. I would leave it like it is. Looks fine to me and it is working . I myself would hate to mess that up. Alex Meissner is who I was thinking of. I dont know if it is the same person. In 1913 A Meissner (MeiBner) invented a oscillator not unlike Armstrongs that we are familiar with. I found a reference that said he had used the opposite layout Armstrong did but otherwise the circuits were similar especially in operation. So I went looking for a schematic and in the English speaking internet could find nothing other then verbal mention of it.So I went on a German language section of another internet radio group and asked auf deutsch (in German) because I wanted to see if it was so and perhaps whip one up just for fun. When you said yours was a Meissner circuit I was intriqued so did a little searching and found a few references to your rig out there on the web including a youtube video but from my home dial up I cant load it as it is over the servers ability to deliver most days. I will go to a WIFI hot spot though and watch it. My hat is off to you. Thank you for sharing.

Don, you are on the right track with Alexander Meissner. If you have the
2009 AWA Review, you can read an article by Mike Murphy, WU2D abt
the Meissner osc, etc. If you don't have it I might be able to scan it for you.
It took a while to get a signal coming out. But when I heard some noise on
the rcvr, it encouraged me to keep tinkering...plus I really wanted to get
something working on 160 besides the normal '29 Hartley. Anyway, it was
fun and I'm happy with the outcome. Yeah, I'm tempted to leave well enuf
alone...hi. I am just now getting ready to re-build a 2A5 osc, from 1933
'RADIO' mag. It's working pretty good, maybe not as efficient as I expected,
but well enuf. Hope it works at least as well after the re-build. If you need the
scan, let me know.

And so???????
donVe3LYX

GM Don and all,

Tks to very good condx, the S reports were 8s and 9s with 3 watts out. Ts were also 8s and 9s. Nil chirp. Windy, but signal upward creep was abe to be noted, but not found quote, "objectionable". All this was at 3843 with the resonate point of the grid coil / valve at 3534. That is, well away from point of optimum signal quality.

If anyone wishes to SKED tonight or Friday at 7:30PM on or above 3615 I am available.

73, Lou

Lou, This is over the top! I just sent the photo to my brother in law in upper NYS. Mike Varley. Mike is by profession an Electronics Engineer. I am sure he will find it interesting. I am around all day today and this evening so if you want to do a QSO tonite on or about 3615 I am up for it. I am pretty sure the rat trap will go there and will check it out immediately. I might want to try something too. BTW I have a 1927 Radio News with an article entitled, Circuits Favoured by British Listeners. Might as well go all the way and build a matching receiver. I can copy the schematics for you. One needs no B battery supply. It is a three tuber
Now I see I need to find a 1920 Deutsche Rohre (German Tube) and build a simplified MeiBner (Meissner) Sender.
That is a very unique looking rig. You done well OM

Will try. Final session tonight, exam Saturday. One student took the exam in another town last week; passed Technician and General!

Bugsy

13023. Grid-cathode short repair?

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-03-24 21:39:42 UTC
From: aflowers@frontiernet.net
Topic: 13023 Message: 13023

I have a UV-203 with a grid-to-filament short. It would make a nice display tube, but I have heard of people opening such shorts by discharging a cap across the offending elements or similar tricks. I'd like to hear from anyone who has been down this road or can point me to a good resource. No, I don't expect it to work, but I see little harm giving it a shot.
Thanks!
Andy K0SM/2

I don't think that "trick" would work for a transmitting tube due to the high peak voltages between the grid and filament.I have had success by whacking tubes against the palm of my hand to correct internal shorts of tubes with poorly supported internals.
Make sure the filament isn't broken. If both broken ends are dangling and touching the grid, the filament can still light.

Ich habe nicht so viel bezahlen. (I have not so much pay.) It was tested and posted for sale on Ebay De where I have had an account for many years. It was made by Valvo which is a Hamburg De Company.It is later production I think then Mike's picture but still ballon and old style. And the shipping was reasonable. (Less then we pay here.) I suggested to the XYL we go an get it but got no response although we have been there several times. I have no Socket (Sockell) but I have made them before. I am sure not real powerful but If it works I am happy. 1.5 volt heater so that should be easy. I have a regen with a pair of 26 tubes and have no trouble keeping it lit. I have to replenish my stock of copper tubing as I am currently out. I think I will use 1/8th this time as a MeiBner has a lot of coils. I took a chance on it based on what I know about the Deutsche character. Lying is almost impossible for us despite other flaws so there is a pretty good chance it is as it says it is. Time will tell.

510.00 EUR = 756.10 CAD !

Thank you, Mike for taking the time to gather all that. I have been musuming over acquiring français & Deutsche valves. If $756 is an indication, I had better stay with the English valves....cheap, compared.

Don, With a RE84 you'll be King.

Sieben drei / Seven - tre , Lou
Don & Joe.... Not too suprisingly, it works. The 530S is tuned up on 3615 realy to go at 8PM.

Is it coming from Germany? I buy a lot of collectible tubes from Europe and they have always gotten here without a problem. There was one exception, but, the seller packed it very poorly. 73 – Mike

I have bought tubes from England before for my No 9 (not no 19) wireless set. The price was excellant and delivery very good. I bought a complete set. Have also bought PT 215 transmitter tubes for a T 1154 based project with good success. This one while found on Ebay.de is coming from Austria. What is really spooky is I think I know or at least have had contact with this guy before but in my automotive career. Just from his name and the invoice but I will check further when I have the hard copy in my hand. Back then he told me he was in the Audio Amplifier business. We shall see. Kinda freaky if it so. I am hoping it isn't so. That would be a good thing. ;>)
BTW I have had an s8 + noise level here for a few days. I first noticed it the night we were all on SSB. but when today it was unchanged i grabbed a portable Sw analog RX abd went on a hunt. found it. A new Walmart sold small current smart battery charger. It was transmitting noise in the middle of 80M and radiating it to everything plugged into that side of my panel as well. Noise level now is down a whole bunch. After unplugging it I checked and it read 1.5 S units. It is higher at the moment but still no where near where it was before finding it.

My noise problem solved and time on my hands I will be firing up the Rat Trap rig on 3615 and testing (CQ test) on the half hour mark 530 630 730 etc till I get too sleepy. I know it is easter weekend and everyone is probably busy but here it is quiet so if anyone else needs something to do please listen for my signal. Replys in SSB or Cw are fine. I will be modulating but will start with CW test sig first. (VVV VVV VVV) I don't have a lot of power but if conditions are favourable its hould be enuf.

Ok here is the regen. Many thanks to Don for helping me sort it out via email. My first attempt was less than successful. I had never done a SW regen before. So after lots of questions and answers I came out with this. The national dx capacitor is cut down to basically two plates. The stator actually has three because I didn't feel like taking it all apart again and it was easier to take out rotor plates. So I stuck the last rotor plate on the outside. I was concerned about losing too much C so I mounted a Pilot midget on top. It stays near open for 80m. The 3 meg grid leak and .00025 sangamo capacitor duo is threaded onto the dx post. Tubes are Cunningham ux301-A but I originally was using some older bakelite bass uv's. I realize the plug in coil type does not match the period exactly for these tubes and sockets, but it's what I had handy. The rheostat is for filament control while the smaller pot below is the resistance for B+ regeneration control. With this setup I can power the Atwater Kent speaker borrowed from my model 40 pretty well. Many signals can easily be copied from the next room, including SSB. If I could improve one thing it would be selectivity, as the bandpass seems to be much much wider than I am used to. But it works and thats a lot further along than I was so I'm happy.

13066. Antenna TesT

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-01 10:41:01 UTC
From: dulmagedon@...
Topic: 13066 Message: 13066

I bumped into yet another bare essentials builder last night. We decided to do as he called it a duet. So at a 11pm here I hooked mine up to the new Hb vertical 80/40 and called. Despite heavy QRN (lightning crashes) for both of us the signal got thru fairly well. The distance was about 400 mi according to QRZ and the power as many know is not huge so I am quite pleased , especially with the performance of the new antenna.
That is the good news. The bad news is my Bootoon GDO died. I had hoped it was just the cable but it isnt. I suspect something has come loose in the tiny tube in the head. Been going to make a Fet one for years. I guess it is time. Old unit will still make a nice well regulated PSU so all is not lost.

Don, get into the thing and troubleshoot it to positively identify the failure. If it is, in fact, the 955 acorn tube that died, I can mail you another.

73 Bill K4JYS

Bill,

What was the advantage over using 'hook-up' wire of the time... No idea regarding advantages. As to why used, here's a guess. You've problem noticed that the pre-1925 RX and TX look more electrical then electronic. The early wireless researchers and designers were electrical engineers and that background, to me, shows in their radios. For example, buss bar "wiring" is common in transformer stations then and now.

Perhaps there is a cognoscenti here that will tell me I'm all wet...and why.

73, Lou

13072. Wanted: Restorable Meissner Traffic Master Receiver

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-01 17:26:16 UTC
From: Roger Kuchera
Topic: 13072 Message: 13072

Today at 1:19 PM Gentlemen, I am looking for a restorable Meissner Traffic Master receiver. I believe they were basically sold as kits,circa 1938 -1943. They had 14 tubes in them. By restorable, I mean a unit that doesn't look like it took adirect hit from the USS New Jersey!

I would trade this for my National FBXa with an original PSK preselector. The FBX comes with a set of6.3 volt tubes and several sets of coils in a homemade coil holder. There are a few spare coils and someorphans. No power supply or speaker. Both the FBX and PSK have been recapped with modern parts. Imodified the PSK (reversible) to shunt feed the plate of the RF amplifier in the preselector.

Digi pix are available. It has been repainted in Black crackle. Other information available on request.

Please contact only by email.

N8AFT Lane, Columbus Ohio.
I have had the GDO apart already trying to sort it out. I had thought it was intermittent cabling because it works and then doesn't but when I tested it it checked out fine no matter how I twisted it. I realize it is a pretty high quality piece but right when you really need it it quit. It may have to sit on the shelf for a bit while I cool down. It works for a bit then stops then just when you are ready to through in the towel quits again. I will set it aside for now. I am going to make a FET one anyway and have been for quite sometime since I would have to buy absolutley nothing to do it but I did like the Booton very much. Let me cool off and I will go from there. Thanks for offers of help.

Dean sounds great!
The wind is really blowing today (Dean is about 30 miles from here so he's dealing with the same stuff) but his frequency is much more stable than mine. I managed to work him by loading my 40m dipole as a Tee, using my 40m coil as the antenna link and clipping in an 80m plate coil that looked about right. I love this stuff!
I'll also hang around on 3560 when I'm in the basement with the wide filter on the RX. We still have a couple hours of light here.

Don, I just saw your note (7:25pm). Sorry about that. I made a couple of calls just now on 3561.

Nice QSO with K0SM and NO3M among a bunch of SKCCers. Not bad for a watt or less (B+=200v, Ip=16ma on two parallel 27s). Coupling is very loose.

I have a lot to learn. Seems like magic to me! Thanks to all for your help.

PS Cathode keying gives 22v across the key; close to what I measure for grid bias.

73, Dean, NW2K

Common mode of ops here. A good regen like a twinplex is no handicap. Tis an advantage and I don't care what you have R390 SDR whatever. It will still hear more when set up right with an experienced operator. (yes,Virginy, I have some SDR ;>) ability here) If you build it with bandspread and then put the vernier on the bandspread cap you can get some pretty fine tuning. Or use PT which is very fine. Ok I will go back in my cave now.
However did use a regen several times for ops even in the last few dys including copying Dean. he was about twice as strong on the regen and a 10 inch loop as on the trio Com RX and a beverage. the TS830S wasnt even in the ball game really.

Well I had imagined that the cut down dx would be enough band spread but I guess the plates are too large for great fine tuning. I used that cap because it was already mounted to that section of panel with the velvet vernier. Hence the rather strange looks of the set.

Hi Dean, Don, et others,
 Congrats on your success with your new AWA type rig, Dean! Unfortunately, I was unable to listen to your test xmsn, due to thunderstorm activity.
 With regard to the RBN, I have never seen an RBN response, while using my 40m "29" transmitter. The power output is only a bit over 1 watt, from a single 27, with only ~ 200 volts on the plate. The feedline loss is large due to the use of a long run of old RG-58 type coax. Nevertheless, there were a number of "sharp eared" BK participants that were able to copy my feeble sig well enough to log some QSOs. The point is, don't allow the lack of an RBN response discourage you.

always copyable up here! I think also, RBN will 'ignore' a signal that has a certain level of chirp / instability. As well, it wants to hear near-perfect / machine-like code so sending by hand might also limit the number of spots.

I guess I hadnt thought about the fact that more spacing would have the same effect as removing plates. I will have to do that. Don, it is equipped with a velvet vernier. The chopped panel and dx cap was an ebay find originally planned to use for a Hull hartley, but Ive since found bigger DX's more suited. I was toying with the idea of a reduction into a reduction but I can easily move the rotor plate back and add capacity at the pilot.

Im a little ADD with my projects and Im also working on a P-P hartley running two 203-As.

PP 203! I will watch for the coming glow in my antenna. You could also just put a cap in series. The resulting total cap will be less then the smallest cap in series. I have to adjust my coil a bit on my new one. Only goes to about 3725.

Larry and Mike, So I gather neither of you think it would be a stretch that that submini tube is failing? I will have to make a spot on the bench and do some further testing but I think I do want to fix it. However last night after supper i found an unused RS circuit board, a small coil form and raided my parts bin. I actually had everything needed to build a 80/40m Gate dip osc in stock so I did a build using a circuit from a 1999 AWA OTB (vol39)(intended for broadcast band but I bent the specs to suit my needs.) I didnt mount the meter as I would prefer a LED . Somewhere I have about 30 LEDs "Where" is the big question. So if I didnt mess up in the build it will buy me some time while I give the Booton serious look. Thanks for you offers. I will let you know what I find.

If you haven't already, check the obvious - plate voltage (the VR tube should be lit, for example), resistance of grid leak, good, clean connections to the coil and capacitor rotor, etc.) Also check continuity of the 955 heater. If everything around the 955 looks good and it's still not oscillating, at that point I'd suspect the tube.

From: aflowers@frontiernet.net
Topic: 13107 Message: 13107

I'm looking at a schematic for a Browning-Drake 4-tube broadcast receiver, probably 1926-27. It's a regen design with a neutralized front-end RF amplifier ahead of the detector circuit, followed by two stages of AF. My understanding is that the front end amplifier would both isolate the antenna from the oscillator and provide some attenuation of the oscillator from radiating. It looks B&D concept dates back to at least 1923.
So my question is, how far back does the use of the RF front-end amplifier (in any form) go in amateur "shortwave" (200m and down) receivers? I think the National SW-x series might have had one in some designs, c. 1930. Has anyone seen published examples of this in amateur shortwave designs before 1925? It seems that scaling the "regenaformer" coil for the for the shortwave bands construction might be a reasonable experiment for a ham in the mid 1920's, but I'm curious if anyone actually tried it back then.
Thanks,
Andy K0SM/2

Read the mail tonight. I used my upstairs beverage and the Trio 9R-59. I heard one of my most favorite words too, "DIVIDEND" . Now entering my 19th year of retirement (and only a cookie jar, no work related pension)that words still gives me a warm glow.
It was Joe --IBX who encouraged me to give the Trio another chance. On the beverage with the original speaker it does a pretty good job. Turns out it doesn't like any of my earphones. Obviously I have some mismatches but I have no idea what it should have. Anyway I am still listening to Larry and Joe GMS.
Spent much of the morning trying to improve my 211 TNT. Made some progress I think. Then in a moment of foolishness I plugged it into the cathode modulator (6y6) and was surprised to hear how it sounded. Got a test coming up between 10 and 11 tonight to see if it gets out. 7110kcs beginning in Cw then switch to phone for a few minutes. For those restricted CW reports are more then welcome. Wish I knew the exact time but I don't yet.

Read the mail tonight. I used my upstairs beverage
and the Trio 9R-59. I heard one of my most favorite words
too, "DIVIDEND" . Now entering my 19th year of
retirement (and only a cookie jar, no work related
pension)that words still gives me a warm glow.
It was Joe --IBX who encouraged me to give the
Trio another chance. On the beverage with the original
speaker it does a pretty good job. Turns out it doesn't
like any of my earphones. Obviously I have some mismatches
but I have no idea what it should have. Anyway I am still
listening to Larry and Joe GMS.
Spent much
of the morning trying to improve my 211 TNT. Made some
progress I think. Then in a moment of foolishness I plugged
it into the cathode modulator (6y6) and was surprised to
hear how it sounded. Got a test coming up between 10 and 11
tonight to see if it gets out. 7110kcs beginning in Cw then
switch to phone for a few minutes. For those restricted CW
reports are more then welcome. Wish I knew the exact time
but I don't yet.

13111. 40M test

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-05 10:13:26 UTC
From: dulmagedon@...
Topic: 13111 Message: 13111

I have been working on my TNT 211 rig trying to get it to sound a bit better. I split the Bneg supply right in the PSU (resistive Y to heaters) and moved the keying there as well. I changed the gridleak and its method so as not to unbalance the cathode/heater circuit and made a capacitive Y for tank coil ground return. All helped and bit by bit I am making progress. I am able to work fairly decent distances and I monitored it on AM just to check hum modulation. Perfect? No, but pretty good. Certainly a big improvement over as built was. It was really pretty quiet and was sitting just above the cathode modulator I built for my ARC5 stuff. So I tried it. Sounded pretty good here. I need a on air test. Not too far as power in phone mode is reduced. I need someone used to AM with an AM receiver. I am set up on 7110 on my rx but have been told it is actually 7108. So around 7110kcs. I don't know what is the best time on 40M. Probably early afternoon. Late night it changes in a few seconds to high noise so I think afternoons would do better. It would be quick and painless. Probably under 5 minutes after contact is established. I have no SSB function in Studio B where all the good stuff is. So would call CQ Test in CW then switch to AM mode. Need a listener who will also switch their rx to AM mode. Any willing ears would be a big help. Then I could put it behind me ready for the next big adventure.

Thanks Matt,
I came across the same article in my travels last night. There's not concrete design in there, but the principles were obviously in circulation and one could definitely apply them.
I think it was the Jan 1925 edition that had an article on coil design by either Kruse or Hull that showed a picture of a zenith tuner that had its coils wound for "shortwave" operation using spaced windings. The thrust of the article is about the merits and engineering tradeoffs of different coil winding designs, and they used this modified commercial tuner with a cylindrical coil to show that there's nothing inherently wrong with boring cylindrical inductors for amateur work so long as the parasitic capacity is kept in check. The author suggests that amateur's preference exotic spiderwebs and basket weaves have more to do with aesthetics than function...which is probably just as true today!
I didn't identify the tuner in the picture, but it looked like it might have been a neutrodyne-type circuit. Whatever it was, it was an concrete example of amateurs reusing BC receiver in late 1924 (when they would have sent the QST article to the publisher).
It seems reasonable to me that amateurs might have taken something like a common Browning-Drake kit or similar and wound the coils for 200m operation. I definitely remember coming across a "reflex" circuit described in QST that had a postscript by the designer that said to halve the number of turns to put it on 200m. (I can probably dig it up the reference for that if someone wants it. I'm almost sure it authored by Mr. Grimes, who sold reflex receivers commercially at the time.)
Andy K0SM/2

13118. The UV199 Transmitter Project

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-05 15:55:37 UTC
From: dulmagedon@...
Topic: 13118 Message: 13118

As you may remeber I was trying to build a transmitter with a UV199. First one I got was dud so I bought one from a vintage tube guy. It seemed to test Ok in a test jig but i could never get it to go. I rebuilt the Tx in several different forms but it refused to go. So i thought perhaps I did something wrong and I built a 201 to UV199 from an open circuit tube I destroyed to get the base. It worked and very well. nice note , no chirp. Some of you worked me on it. I suspected the UV199 doesnt make a good Tx tube and was and am very suspicious of the article I read claiming they had tried one. A few days back i saw 2 NIB uv199 on ebay. I got them cheap thinking just in case it was worth a try. The instructions for radio builders in the 1910s and 1920s were wrapped
around each tube and since they were not the same brand I also had two sets of instructions. I read them. I had said to myself once when working on this before that ot acted like a 45 with too little heater voltage. (They often don't want to start unless at 2.5 volts.) The UV199 is rated at a filament voltage of 3v. You will find all kinds of warnings about being careful with them all over the WWW so I was most careful. I already had many used a new pair of c batteries as my source , checking with my digital meter to be sure they were supplying 3 volts. Actually they were just over when fresh at about 3.1 volts for the pair. With that in mind imagine my surprise as I read the instructions telling me to power the filaments with three No 6 batteries in series and a diagram showing how. I am old enuf to have bought No 6 cells new so I knew that is 4.5 volts not 3volts. I double checked the spec sheet. Yup, it said filament 3 volts. I opened the other tube box and unraveled it. Its paper said and I quote. Heater voltage from 4 1/2 to 3 volts. THREE is the minimum. My gut was right. I took out three new D cells and soldered them in series with hook up wire. I tried it again first with 45 volts B power then just over 100 volts B power. Still nothing. sounded like it wanted to go but no joy. Poped in the adapted 201A and supplied required voltage. Worked perfect. I decided the UV199 was awasteof time (and money.) So I dismantled the little rig so it wouldn't be sitting there taunting me and I could use the parts for another project.. I already have several Hartleys so didnt really need this one. This morning I was cleaning up the shack and found another UV199 tx I had built but an Armstrong circuit . I had thought that would have been the first tx circuit so I whipped one up using a uv199 to 201A adapter I had for a socket. Before ripping it down I decided to pop one of the new tubes in and the proper 4.5 heater volts supply and try it. I hooked up the 45 volt supply and turned on a SW poertable on 40M. Mmmm that sounded good. You get to know the sound. don't ask me to explain. You just do.I grabbed the set and pushed the key searching for a signal. There it was 7084kcs. I Keyed it to be sure I wasn't dreaming then searched for it on the DX394 shack RX. Yup there it was. Not real powerful but it is working. I installed the old Pilot socket and wired it up and tried. Yup still working. 1.87 ma, 134 volts B and 4.5 heater volts. Not very practical for Dx but ok for a Cw walkitalkie perhaps. Anyway that is what happened here today. And it wasn't anything I planned either.

201 to UV199 from an open circuit tube I destroyed to get
the base. It worked and very well. nice note , no chirp.
Some of you worked me on it. I suspected the UV199 doesnt

make a good Tx tube and was and am very suspicious of the article I read claiming they had tried one. A few days back i saw 2 NIB uv199 on ebay. I got them cheap thinking just in case it was worth a try. The instructions for radio builders in the 1910s and 1920s were wrapped around each tube and since they were not the same brand I also had two sets of instructions. I read them. I had said to myself once when working on this before that ot acted like a 45 with too little heater voltage. (They often don't want to start unless at 2.5 volts.) The UV199 is rated at a filament voltage of 3v. You will find all kinds of warnings about being careful with them all over the WWW so I was most careful. I already had many used a new pair of c batteries as my source , checking with my digital meter to be sure they were supplying 3 volts. Actually they were just over when fresh at about 3.1 volts for the pair. With that in mind imagine my surprise as I read the instructions telling me to power the filaments with three No 6 batteries in series and a diagram showing how. I am old enuf to have bought No 6 cells new so I knew that is 4.5 volts not 3volts. I double checked the spec sheet. Yup, it said filament 3 volts. I opened the other tube box and unraveled it. Its paper said and I quote. Heater voltage from 4 1/2 to 3 volts. THREE is the minimum. My gut was right. I took out three new D cells and soldered them in series with hook up wire. I tried it again first with 45 volts B power then just over 100 volts B power. Still nothing. sounded like it wanted to go but no joy. Poped in the adapted 201A and supplied required voltage. Worked perfect. I decided the UV199 was awasteof time (and money.) So I dismantled the little rig so it wouldn't be sitting there taunting me and I could use the parts for another project.. I already have several Hartleys so didnt really need this one.
This morning I was cleaning up the shack and found another UV199 tx I had built but an Armstrong circuit . I had thought that would have been the first tx circuit so I whipped one up using a uv199 to 201A adapter I had for a socket. Before ripping it down I decided to pop one of the new tubes in and the proper 4.5 heater volts supply and try it. I hooked up the 45 volt supply and turned on a SW poertable on 40M. Mmmm that sounded good. You get to know the sound. don't ask me to explain. You just do.I grabbed the set and pushed the key searching for a signal. There it was 7084kcs. I Keyed it to be sure I wasn't dreaming then searched for it on the DX394 shack RX. Yup there it was. Not real powerful but it is working. I installed the old Pilot socket and wired it up and tried. Yup still working. 1.87 ma, 134 volts B and 4.5 heater volts. Not very practical for Dx but ok for a Cw walkitalkie perhaps. Anyway that is what happened here today. And it

wasn't anything I planned either. donVe3LYx

Ah you read my mind. I thought I need a regen. Since the circuit is the same other then phones and regen control It should be ok. It was my impression the UV199 didnt have enough inherent feedback or internal C perhaps to function in a conventional circuit well so I figured with the Armstrong I can add feedback till it can't refuse.

Cool. You could make
a real QRP rig then. Maybe 1/2W to a watt. There was no
reason for them not to work as they are used in regens. 73

13136. 211 TNT Experiments

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-06 10:59:20 UTC
From: dulmagedon@...
Topic: 13136 Message: 13136

I have been working on my 211 TNT to improve its performance for the receiving station. I have made some progress but as I mentioned I got tempted by the Cathode modulator and tried it out. Seems pretty good as I said and I had tried to put a test together to try it on 7110kcs. I choose that freq because I knew I could tune up there from my use of it in recent AWA sponsored events which allowed higher power rigs. Since no-one was there for a test I began to search and see where would it actually tune to. Much to my surprise all the way to 7295kcs without a problem so I will just wait for an opening in the AM window and give it a shot if I can get my foot in the door with a potentially PW signal as they often call it. I didn't expect it to tune up there but it does.

Hi Steve et all, I understand that the RBN would not function well with a sig that chirped excessively, but I don't believe that chirp was an issue, with my situation--I believe that the added feedline loss that was associated with my antenna relocation, is the major issue. I am reasonably cerain that we have not achieved a BK QSO, since that relocation was implemented. 73 de ron n4gjv

always copyable up here! I think also, RBN will 'ignore' a signal that has a certain level of chirp / instability. As well, it wants to hear near-perfect / machine-like code so sending by hand might also limit the number of spots.

Andy knows a bit about RBN ignores and how that is done. What I know about that I learned from him. twas interesting what he had to say.
All I use RBN for is to see where the band is open to. I doubt I could ring its bell without my AMP on and almost machine style CW.

Larry,
NE1S is a very short callsign. This does two things to your advantage:
A) Fewer bits of information to get right.B) Assuming drift is a function of time only, there is less drift over those bits.
Here's my advice if you want to test with the RBN:
1) Send faster, so long as you have a reasonable fist (per item B). Good spacing is key.2) Send "TEST K0SM K0SM TEST". You really need your call twice and the "TEST" is keyword that skimmer will recognize as a "CQ" message. You may need to do this a few times if you don't have a big SNR and/or have an long or unlikely callsign. Don't change frequency. Yes this looks like a contest CQ, but on a weekday its unlikely to gather much attention unless you find yourself on during the CWT or one of the evening sprints. It's what skimmer likes to see. 3) Send below x.045 if you can, and certainly below x.090. More skimmers are listening increasing the probability of being heard. Yes, I know we didn't all design our TNTs optimally there...
Also, CW skimmer is usually configured to include the prior probability of the callsign (i.e., "is the callsign a likely?") Things that make a callsign likely would to be prevalence of calls "similar" to yours and/or your presents in the super-check partial database (i.e., you've done some contesting with that callsign in the last few years). skimmer can only see certain portions of the band at once, typically in 48, 96 or in a few cases 192 KHz. They tend to cover from the bottom of the band, so the higher you are the fewer skimmers are able to hear you. There are very few watching above 7100, for example. You can see a the current list of active and inactive skimmers here along with their frequency ranges:

Many tks for the RBN info & hints Andy & Larry! I should have mentioned that I did have good success with RBN responses on 160m & 80m, using the same fist, etc----it is only on 40m that I had a problem. The lack of RBN response was mirrored by my results, during the BK fun-fest. The list of cwnr (called with no reply) BK stations was much greater, percentage wise, on 40m vs the 2 lower freq bands. Tks agn & vy 73 de ron n4gjv

always copyable up here! I think also, RBN will 'ignore' a signal that has a certain level of chirp / instability. As well, it wants to hear near-perfect / machine-like code so sending by hand might also limit the number of spots.

> Here's my advice if you want to test with the RBN:
>
> 1) Send faster, so long as you have a reasonable fist (per item B). Good spacing is key.
> 2) Send "TEST K0SM K0SM TEST". You really need your call twice and the "TEST" is keyword that skimmer will recognize as a "CQ" message. You may need to do this a few times if you don't have a big SNR and/or have an long or unlikely callsign. Don't change frequency. Yes this looks like a contest CQ, but on a weekday its unlikely to gather much attention unless you find yourself on during the CWT or one of the evening sprints. It's what skimmer likes to see.
> 3) Send below x.045 if you can, and certainly below x.090. More skimmers are listening increasing the probability of being heard. Yes, I know we didn't all design our TNTs optimally there...
>
> Also, CW skimmer is usually configured to include the prior probability of the callsign (i.e., "is the callsign a likely?") Things that make a callsign likely would to be prevalence of calls "similar" to yours and/or your presents in the super-check partial database (i.e., you've done some contesting with that callsign in the last few years).
>
> skimmer can only see certain portions of the band at once, typically in 48, 96 or in a few cases 192 KHz. They tend to cover from the bottom of the band, so the higher you are the fewer skimmers are able to hear you. There are very few watching above 7100, for example. You can see a the current list of active and inactive skimmers here along with their frequency ranges:

13146. Rheostat question

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-08 20:12:27 UTC
From: Louis Vermond
Topic: 13146 Message: 13146

Hi,

I am searching for a filament rheostat to be use with a Marconi-Osram LS5 valve. Test findings below...

LS5 Fil. voltage operating range: 4.25 - 5.25V DC at 0.8 A average

Readings using 5 ohm rheostat:

4.25 V / 2.9 ohms

5 V / 1.8 ohms

5.25 V / 1.6 ohms

Assuming an average 1920s RX rheostat and for least amount of winding heating, 3 ohms maximum would be the ideal.

Agree? No? What then please.

Tks, Lou
VE3AWA

well first the low voltage for sufficient heat is wonderful for a RX which is intended to be used hour on hour. all year long. A Tx often doesn't run well on minimum heating as as it transmits it loses a bit of that warmth so general they run better near the top of their rating. We have to remember the factory rating, recommended rating is 4.25v (least it will run with and in TX mode probably wont sustain running long) As you may remember from my recent posts my UV199 would not run at is minimum even a bit above it. Ie It wouldn't even start at 3 volts or even 3.1volts. Its specs are given as 4.1/2 volts to 3 volts in both sheets that came with the tubes. I don't care what the internet says or your tube manuals that is what the enclosed spec sheets said for both NOS tubes) So if the manufacturer says it requires 5.25v to 4.25 volts then anything in that range is fine. Are you a better man for running it at 4.25 v then 5.25v? No. Both are with in spec. And in spec is IN SPEC. Would it die if it got more? I understand you don't want to go there so we will forget that. Point is any of your voltages are with in Manufacturer specifications and there is no prize for erroring on the low side. In spec is sufficient care. And no reason to go above the high side. I imagine if my experience has any relevance is the performance difference between 4.25 v and 5.25 would be fairly dramatic. It is with some of the tubes I run. And I know any manufacturer worth his salt includes a fudge factor for accidental momentary errors. Anyway you said "any thoughts." Those are mine.

13148. RE: [AWA Group] Rheostat question

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-08 23:13:45 UTC
From: Steve Flood
Topic: 13146 Message: 13148

Three ohms would give you the most precise adjustment ability since you have use of the full rotation of the rheostat.

Up to five ohms still seems reasonable.

I think if the rheo is in series (not shunting the supply as a voltage diver) there is no worry about winding heating since the wiper shorts across the 'unused' windings.

From: dulmagedon@...
Topic: 13149 Message: 13149

I fired up the FET GDO (From AWA yesterday.(from OTB Vol 39 No 3 pg 50) It works ok but is no Booton. Not even close. It will buy me some time while I trouble shoot the good one. Cost me no actual $ so I'm good. The LED indicator system works but takes some getting used to.(As Larry figured I might not like it.) I gestimated the coil and hit it almost bang on. Covers 80m and 40M which is what I wanted. I just need it to ball park the coils and only for 40m and 80M so even though that is wide tune it serves my purpose. The tuning cap I used was a transistor poly variable from my junk box. It has a scratchy center contact so I ordered 10 from Argentina to replenish my QRP stores. They will probably arrive "sometime" but I am ok for now. I also scored a 210 tube so I'm hoping it is here in a few days. Want to compare it against my 45s. 45s make good power but are somewhat unstable when used for oscillators so I have discovered (210a s while not powerful are rock solid performers (I did my testing in the same rig just adjusting the heater voltage for the 45 or the 201A. I suspect the 210 being intended for tx may be better built mechanically. Now I have to make the heater supply for a 210. Maybe somday a 201A210 Mopa! Checked into the Old Military Radio net with the No 19 this morning. Just made it. ??? never mind. Going to try some AM ops today with the No 19 and the ARC5 and its newly reworked PSU. Am watching 80M for victims now but will switch to 40m soon as the bands change. Also want to see if I can improve the No 19 PSU a bit. Can't hurt to try. the ARC5 one os now quieter then the No 19 PSU
Anyone want to try anything today I expect to be in the shack most of the day and can listen if needed.

Have a gud day all. 73 DonVe3LYX.

13168. Info on early REL radios?

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-10 19:21:35 UTC
From: Art Lebermann
Topic: 13168 Message: 13168

Does anyone in the group have info on early radios from Radio Engineering Labs ("REL")? I have what I believe to be a Model 278 receiver (from 1931?), but have found very little information. I'm looking for a schematic, and any other data that might be available.

Thanks!
Art Lebermann

Ya know, I had a hunch... But why only one bidder?!

REL became more sophisticated in their designs and workmanship inside and out with this. Quite impressive. Comparing looks, the SW-3 is an industrial box.

Hope that Art and you fire them up and give the Group a report on its electrical comparison with the SW-3.

Well, your hunch was better than mine. I had assumed that Art bought it, till I learned otherwise. I looked in the house and it is not in here, so, it must be out in the shed. It is in the 60's, so, I may go out there in a while and see if I can locate it. It will be a while till I will be able to make comparisons, or even hook up any of my OT rigs (HI). Need to do a lot of organization and will need my sons help for that. Anyway, after this week, I will be retired and once I get used to the idea, I hope to get back into just playing radio and selling on eBay. Why only one bid, I do not know. Maybe it was a BIN, or, maybe no one else wanted it as his starting price was what I paid, which was $495. 73 – Mike

A pretty radio indeed, but my guess would be its performance is inferior
to the SW-3. For one thing, there is no TRF stage. For another, the
design appears similar to the Gross Eagle, of which I've had the
opportunity to try out a couple of examples. My impression of that set,
although it worked OK, was that it was a toy compared to the SW-3.

Mike and the Group....

Here's a little more background on this radio. I'm a member of the California Historical Radio Society, and I purchased this radio from one of our members at a swap meet – about five years ago. I had no idea of the value, though I did recognize the "REL" logo. My friend didn't know much about it either, which is probably why we agreed on a price of $50 (yes – $50!). It's been sitting on a shelf in my shop since then. I'm in the process of organizing my collection, and "re-discovered" it. I thought it would be interesting to see how it worked, but found very little info on the Internet. As a member of AWA, this seemed like a good place to post a request. It looks like my unit is complete, except for missing the dial scales behind the "regen" and "gain" controls.

Does anyone have a schematic for the 278? I can trace the circuit, but a schematic would help! I do have a National SW-3, so I can make a comparison test – when I get them both operating. FYI – I'm a broadcast engineer, recently retired from full-time work with Cumulus Media in San Francisco. I'm now doing independent "contract" work for Bay Area radio stations, so I'll have a little more time for the radio restoration projects.

73,
Art Lebermann

13184. 1BGF Tuner building

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-11 23:03:07 UTC
From: aflowers@frontiernet.net
Topic: 13184 Message: 13184

I'm intending to build a 1924 style station. It's an interesting time since this is the year that the 80, 40, and 20m bands were opened to all amateurs and there is a great deal of interest in building "short wave" receivers that can tune the new bands.
For the RX, the "1BGF" Tuner looks like a pretty good way to go since it has continuous adjustments for antenna coupling and feedback, and I think I would have an easier go of it that dealing with switched inductances and stray capacitances in the (older) Reinartz design. It also seems to be pretty popular. A quick look through the 1924 QSL cards on for sale on eBay shows quite a few "1BGF" or "QST Low-Loss" receivers being used, and the article only came out in February of that year! I'd like to build it for 80m, and maybe for 40, though I have my doubts whether I could get it to work in both places with the same coils. This would be my first hollow-state regenerative receiver project.
Has any one built one of these and have experience or pictures to share?

Hi Lou,
I don't yet have a copy of the February '24 "Low-Loss tuner" QST article. I've just been looking at some pictures and descriptions to figure out what people built at the time and trying to understand the construction techniques involved. It looks like a pretty standard regenerative circuit with the "innovation" of continuously variable coupling and tickler rather than the use of tapped inductances. I don't need to make an exact replica of an exact radio, but rather more of a process recreation to learn something about how one went about it with period parts.
The Browning-Drake "Regenaformer" BC receiver I have here is one that uses a continuously variable feedback, and input gain to the detector is by means of a TRF stage. The typical ham receiver doesn't seem to have this TRF front end in 1924, although there is some discussion of it in the radio periodicals in 1924-25, probably thanks to the popularity of the BD design. I presume it would be "cutting edge" in 1924 to use a TRF at short wave (I think I saw only one card out of more than 20 from late 1924 that mentioned one step RF).
Anyway, the dual-coupling would be very handy to both reduce the coupling between the oscillator and the antenna as well as provide some amount of RF gain.
My only experience with a regen was a solid-state Ramsey kit I built as a teenager I don't remember much about it!
Andy K0SM/2

☐Andy, Do you have to original QST article? Lou
----- Original Message ----- From: mailto:'aflowers@...'%20aflowers@...%20[AWAGroup] To: yahoogroups Sent: 2016-04-11 7:03 PM Subject: [AWA Group] 1BGF Tuner building

I'm intending to build a 1924 style station. It's an interesting time since this is the year that the 80, 40, and 20m bands were opened to all amateurs and there is a great deal of interest in building "short wave" receivers that can tune the new bands.
For the RX, the "1BGF" Tuner looks like a pretty good way to go since it has continuous adjustments for antenna coupling and feedback, and I think I would have an easier go of it that dealing with switched inductances and stray capacitances in the (older) Reinartz design. It also seems to be pretty popular. A quick look through the 1924 QSL cards on for sale on eBay shows quite a few "1BGF" or "QST Low-Loss" receivers being used, and the article only came out in February of that year! I'd like to build it for 80m, and maybe for 40, though I have my doubts whether I could get it to work in both places with the same coils. This would be my first hollow-state regenerative receiver project.
Has any one built one of these and have experience or pictures to share?
Andy K0SM/2

I don't yet have a copy of the February '24 "Low-Loss tuner" QST article.

Andy, I will send directly the rather long article. Anyone else?

I know there was a close reproduction built in the last 20 years or so. I can see the photo of it. Perhaps in an OTB? N4FS...recall that?

Ken, W2BGN (real Old Timer) told me that to maintain the positions of L1 & L3, the knobs/dials were tight up against the front panel.

The 1BGF and Schnell are very similar, the main difference appears to be a split secondary inductance, elaborated upon in the caption below the schematic of the Schnell:

"The two-part secondary completely avoids inter-action between the tickler and the antenna-coupling. Either one of them can be moved around without causing the note to slide around, as is the annoying habit of ordinary tuners."

In that respect, the Schnell is better.

Interesting that the grid leak is missing in the 1BGF schematic and not the Schnell....

There's a addendum in QST March 1924 p. 26 (attached) that specifies the number of turns for the secondary (L2), which was accidentally left out of the February article (24 turns for ham bands).

There I was running my 1930s style station when this popped up on the screen over on the next desk. Would be a lot of fun. Something about using a regen to listen and a period correct matching Tx to transmit that has a special fun. I was at that moment comparing the signals between a 9R -59 Trio com rx and my 6sl7 regen. The Trio being fed by several hundred feet of antenna and the regen on a 10 inch window loop(here is the loop) . No comparison. Regen wins hands down. Was listening to N8AFT, Lane, in Columbus Oh in qso with another VE3. Might give it a shot before turning in and see who I can raise. 3555kcs.
Hope you build it the 24 QST rx or something similar. They are a lot of fun and work very well. My 1920s regen that I use is downstairs with the old rigs. It is currently running a pair of 26 tubes although 01As would probably work better. There is one up here too but I havent had it going for a year or so. Maybe it is time.
A coal Oil lamp or a candle would add to the moment. Hope it goes well for you.

Topic: 13196 Message: 13196

I love regens , I guess that is no secret. Simply put because they really perform. over the many years I have been building them (since about 1964) i have changed some of the things I do. So I will just mention them in case it might help someone else.
Plug in coils. For years one big obstacle was finding plug in coil forms and many a project was on hold as I searched for a new source or made them from old tube bases. Then one day i realized I never changed them anyway. For instance my twinplex while it has coils for 80 40 and 20m has never been used on anything but 80M by me and I have had it something like 34 years or so. So now I don't bther with plug ins but build fixed coils like I do for my TXs as well.
Antenna. When first building I thought a big antenna was the answer. And resonant would be good. Now I know a few feet hung over the curtain rod or my empty gun rack (We are not allowed to display our guns here so other then BB guns it is empty) is more then enough. in fact better .A resonat antenna at its sweet spot may cause a dead spot in tuning as it overloads the circuit.
RF front end. I have built them with an RF stage but no more. Totally unnecessary and a hamper to good performance. Radiation is only a few feet if you run your set right and there is no reason not to. In fact the VFO on my DX60B can also be heard when using PTT if I don't switch to standby as can my No 19s osc if I have another RX on when using it in CW ops. Overblown problem. In a properly run set does not exist as a real problem and your set WILL NOT work better with a RF stage. I no longer build them with one. We in North America are consumed witha "More is Better" mentality. In fact in many instances Less is More!
Tubes. Some tubes are much better suited to Regen ops then others. For instance with 1930s/40s tubes a 6sl7 is a much better choice then a 6sn7. Both work but the difference in performance is surprising. Last one I built used 26 tubes. I think 201A would have been a better choice. I prefer triodes having built with both.

Throttle caps work to be sure but I find them very annoying and prefer a pot to control regen .
You can by the way also build a working regen wth no regen adjustment and I have two of those.

Whatever you decide and whatever you build I would encourage you even if it runs against everything I said. there is nothing more fun then sitting in a dim light in the shack earphones on Hartley or TNT at the ready holding a QSO using your regen. Real radio! I used one as much as possible this year in the AWA events and have one of mine running I think i can safely say almost everyday. Doesnt get any better then that. IMO
Oh yeah, Don't beleive everything you read about them. Ie poor selectivity, Not practical , radiate RF to the neighbours etc. Balderdash to be polite. Based on 50+ years of using one on a regular basis..

I use plate voltage pot for regen. Why did I find the throtle cap annoying? MMMMMMMMM I was just never comfortable with it and it required constant adjustment. My best regens rarely require any adjustment on the pot. I finally removed it from the first one I used it on and replaced it with a plate circuit pot. But still have it on the breadboarded Regen I built. It bothers freq some as well (although not a lot) which the pot does not. I won't monkey with the breadboarded one as it is working and is as it should be and is a classic from the ARRL handbook. I dont use a pot in the screen anymore as I have forbidden myself from building any more non triode regens. They never work as well as a twinplex dual triode. I suspect there are some accidental things that go on inside a single envelope twin triode that are not scripted. Those dang things just flat out work, every time and very well too. Best place for a beam power tube in the mix is an additional final Audio Amp and they do a good job there. IE 6v6 etc. That has been my experience. So i would say if you want to add an extra stagean extra Audio PA would be my pic and my one set has that. An Audio filter can also be included giving you a real decent performer.
BTW got some QRO in today. Was interviewed by the local radio station live. Also very interesting as it is a small outfit and all was visable. Busy place! New experience which is always interesting.

Don, Thanks for your explanation. There's one other possibility which is a rheostat in the filament circuit of battery-type detector tubes. I've used that on an 01A regen. Mike, W6MAB

Subject: Re: [AWA Group] Regen tips from the field

I use plate voltage pot for regen. Why did I find the throtle cap annoying? MMMMMMMMM I was just never comfortable with it and it required constant adjustment. My best regens rarely require any adjustment on the pot. I finally removed it from the first one I used it on and replaced it with a plate circuit pot. But still have it on the breadboarded Regen I built. It bothers freq some as well (although not a lot) which the pot does not. I won't monkey with the breadboarded one as it is working and is as it should be and is a classic from the ARRL handbook. I dont use a pot in the screen anymore as I have forbidden myself from building any more non triode regens. They never work as well as a twinplex dual triode. I suspect there are some accidental things that go on inside a single envelope twin triode that are not scripted. Those dang things just flat out work, every time and very well too. Best place for a beam power tube in the mix is an additional final Audio Amp and they do a good job there. IE 6v6 etc. That has been my experience. So i would say if you want to add an extra stagean extra Audio PA would be my pic and my one set has that. An Audio filter can also be included giving you a real decent performer.
BTW got some QRO in today. Was interviewed by the local radio station live. Also very interesting as it is a small outfit and all was visable. Busy place! New experience which is always interesting.

☐

Don, What kind of pot regen control do you
prefer? Screen grid
voltage, plate voltage, shunt across the tickler coil, pot
in series with a
fixed throttle capacitor, or something else I haven't
thought of?

Also. why is a variable throttle capacitor "very
annoying"? I'm a regen fan too. Mike,
W6MAB

Regen tips from the
field

Throttle caps work to be sure but I find them
very annoying and
prefer a pot to control regen .

I got mine through my older brother Ron who spent half his life selling surplus. He and Bill Ford dealt often at a wholesale level and he told me about them. I don't know where Bill Ford got them but he had several. i suspect Crown Assets as they both used to be accepted bidders at the Govt disposals. I paid $125 for it and it would have been in the 1980s. pre 1985. They look very similar to a R 1155A except don't have the central tuning control. And they came with a 110v supply installed suitable for the admiral's shore office.
I have another neat deal my brother bought back then. A spy locator radio kit from the "old country" . My brother gave it to my Dad who kept it in his office on display. When Dad moved to a seniors home he gave it to me. It is all there , briefcase and all except the batteries. I never had the nerve to power it up. The manual has been translated to english and you cans see the translation has been pasted over the original pages and copied. Probably by Gestetner. I can tell because it is not page 1 2 0r 3 but Blatt1 Blatt 2 Blatt 3 and I can see the edge of the pasted sheets on the copy. (Blatt means leaf or page in German.)
So do any of your sets ever check out or is your basement like the Black Roach Motel (they check in but they don't check out)
BTW Did I see you were retiring . If so congrats. You will begin now the best job you ever had if that is so.

Don –

Very interesting. Could you send me higher resolution photos of that little set? I have enough German sets and manuals to know what Blatt means, HI. A lot of the German WWII equipment have EEIS numbers (Enemy Equipment Information Service) marked on them. Thanks on the kind words regarding retirement. It will be quiet a transition as I have worked all my life. I started working a little after we got to this country, so, by 12 I had a job and later during HS worked almost full time at a radio TV repair shop. I also worked full time throughout college, someone had to pay for it, HI. And of course, ever since. I was on a telecon almost all day yesterday and will be today and tomorrow as well. However, this is my last week. My heart is just no longer in it. I think it will take me some time to get adjusted to my new life, and while I am apprehensive about it now, I know it will be great. Thanks & 73 – Mike

Roger –

Well, the good part is that at least the last 20 years I have been my own boss and the last 15 of that working out of my house. That did not however isolate me from all of the BS, HI. My first 20 years of my real professional career was in ASW systems. So, being in the Navy you may have encountered some of the equipment I worked and designed. Initially most went into a P3. Thanks & 73 – Mike

Both tubes arrived today. An A408 (Re84 eq) from Austria, 1926 variety and a 210 from Quebec. I have to make a socket for the German tube.(4 pin European) and then I can do some more on my Meissner build.
The 210 will find a home quickly I think. In a few minutes after I keep my promise to Mike.

Date: 2016-04-14 13:37:58 UTC
From: Mike Feher
Topic: 13228 Message: 13244

Well, that is really hard to say. They are pretty scarce, but, I do not look on eBay UK, and, they may be plentiful there. I got all of mine in a trade, and when I sold them it was with a bunch of other rare collector type tubes. I would say regardless of filament they should be at least $500 US. 73 - Mike

Mike,

I'm both functional in conversational Pirate *and* married to a Canadian. (Sorry, Lou...I couldn't resist.)

Roughly translated: "What would one expect to pay for such a tube in the condition pictured, with a good filament, etc.?"

The two sections on each of those variables appear to have different capacities, so the voltage node on the coil would not be "centered" in the event someone was considering series feed. It could be approximately located using an RF sniffer, however.

Would the node stay at the same place over the range of the capacitors? Otherwise, the out of phase voltages on each end would would not maintain a consistent relationship and make neutralization impossible.

Yes, the neutralization aspect would only work if both sections were equal.
I use a National DX condenser (175 uuF/175 uuF) to neutralize the 830B triode inmy vintage TX.

Y'all,

I've agreed to give a talk to the Albuquerque, NM Hamfest this August on the evolution of amateur radio equipment, from the beginning to the present day. It will be interesting to see how I fit that into the one hour allotted! I can do pretty well with pictures from 1929 and out, but before then I'm limited to what I can get from the old QST CDs and the postings on the ARRL web site, and those pictures are not very good. I'm really looking for a really nice picture of a high power, rotary spark gap transmitter in action. Can anyone help?

Thanks,

Jim Hanlon, W8KGI

I can do pretty well with pictures from 1929 and out, but before then I'm limited to what I can get from the old QST CDs and the postings on the ARRL web site, and those pictures are not very good. I'm really looking for a really nice picture of a high power, rotary spark gap transmitter in action. Can anyone help?

Thanks,

Jim Hanlon, W8KGI

Hello Jim: Yes, that's quite a time span indeed. I can help with a photo of a nice 1 kW synchronous rotary spark gap in action. It is the one that has been in continuous use at the AWA Museum since we got it in 1952. It was built in 1914 by George Batterson, 8TC (W2GB) a co-founder of the AWA. George got interested in wireless when he copied on-air traffic regarding the Titanic in 1912 and got his ticket in 1914. He lived to be 99 years old and was quite the OT in these parts. Years ago I taught the General/Tech theory classes for our local ham club. George lived across the street from the venue where we held classes and once and a awhile he came across the street and just walked into the class room. I knew then the classes were over for the night as he sat down and just started talking about the old days. You could hear a pin drop. I'll never, ever, forget those times. I don't think I can send the .jpg thru the reflector so I'll send it direct to your .msn address. Enjoy. 73,

Ed Gable K2MP/W2AN
Curator Emeritus, AWA Museum

Y'all,

I've agreed to give a talk to the Albuquerque, NM Hamfest this August on the evolution of amateur radio equipment, from the beginning to the present day. It will be interesting to see how I fit that into the one hour allotted! I can do pretty well with pictures from 1929 and out, but before then I'm limited to what I can get from the old QST CDs and the postings on the ARRL web site, and those pictures are not very good. I'm really looking for a really nice picture of a high power, rotary spark gap transmitter in action. Can anyone help?

Thanks,

Jim Hanlon, W8KGI

Beautiful, Mike!

I keep forgetting to congratulate you on the new (to you) coherer; in these round table nets we participate in so many topics are covered, and my notes are sparse.

Now get back to work! ;-)

73,
-Larry/NE1S

I made a short recording as I was operating a couple of nights ago. This is the Twinplex 12sl7 and is on the white 10" loop in the window. I used a Hipstreet digital recorder which i have no idea where its mic is so i just stuck it up between one earphone and my ear. Sorry for you can hear me fumbling trying to turn it off. Even though this is a poor quality way of recording you can see using it for QSOs would be no trouble at all.

Having lived around many different ethnic groups in this great country of ours, having taught adults at a college level who were long past correcting their English and have finally realized that perfection for any of us is probably not available this side of the grave I am happy when I am spoken too, appreciate the effort no matter how difficult it is to understand and refrain ever from correcting unless someone is searching for the word. When traveling having learned some of my languages after I turned 50 and having learned others long ago and partly forgotten I sincerely hope folks will forgive me when I error as well. And I do, often. As for the concept we should l speak and write perfectly I aint never seen a reason to and hopefully never will. In fact perfect people are boring and often self absorbed. It is the Festus Hagans of life that keep it interesting. I have a very good friend who was unable to learn to read until computer equipped phnes came along. He is the same age as I. He is a plumber by profession and an electrician on the side. His English reflects his up bringing in an non English speaking environment and he uses terms like LABtop to describe a computer BUT he is a genius as a craftsman and very smart on how to find out what he needs to know. He will wire your house faster then you can talk about it and the inspector will find nothing wrong and it will be to current code. He will fix your heating and do your plumbing also top drawer. He is in fact who folks call when no one can figure it out. He understands things. I have no idea how he knows but after 40 years of friendship I just accept it. He has no idea there are two Then/Thans . Heck he can't even swim however I would never stoop to correct him or his English. I seem to find more important things to do. Like finding new tubes and building new radios. The other? It is just foam. Blow it off and drink your beer. It isn't that big a deal. My cousin Martin Dolmetsch said it best the last time I was in his home in Metzingen Germany. He was comentng on my language skills as he doesn't speak or understand English. He said to me in German, Don, Your German is now perfect! I replied , No it is not, to which he said Es ist gud genug.(it is good enough) In my heart I said, Bless you Martin. May you live an extra day. It was a good reminder and one of life's lessons once again confirmed. Don't sweat the small stuff. Gotta quit now. The regen is running and no one listening.

BTW that is a wild looking tube. Hope it gets lit sometime soon.

13265. Changing settings for daily Digest!

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-15 13:40:05 UTC
From: pacquerat@...
Topic: 13265 Message: 13265

Attention group owner:

Some time ago Yahoo offered a display for the daily digest that placed most topics as a hot link in the header. I opted for this from setting within the group controls. Shortly after that change, Comcast in their infinite wisdom changed their email client (yes this was quite a while ago). Fortunately I did not change over this presentation style to the dozen other Yahoo groups I am subscribed. So only this group got the change.

Comcast change to Plaxo/Zimbra does not recognize the HTML embedded in the hot links and simply generates a new email page within the existing one. If one clicks on another link within that new page it does it again, then again into infinity.

This makes even normal navigation difficult.

Now the problem is Yahoo has revamped the groups layout and removed the option to change back to a conventional text presentation of the Daily Digest.. This option does not appear in any other group I use either or at least I cannot find the option.

I once had issues deleting posts in a local Freecycle group. I had to contact the groups moderator/owner and She changed some settings and I was then able to delete dead posts.

However, I have been unable to locate the moderator/owners email to fix my presentation problem.

I am considering signing out for a week and resigning in, same name, etc. but I would like to see what the moderator/owner can do first.

Please message me by looking up one of my old posts and it should show my email address as pacquerat@comcast.net

Please help fix this display issue.

Also, daily digest in any of my groups do not show images, this may be another Comcast issue.

Many Thanks for any help you can give.

Charles –

I checked your status and you are set up for “daily digest” mode now. I do not know what to do to help you. I could remove you from the group if you like and you could sign up again as you suggested and see what happens then. 73 – Mike

Don –

Sorry if I hit a nerve there. It was not my intent. You may recall that in one of Lou's emails he talked about the funny way Canadians speak and spell and expected us to pick on him. All I did was comply, but, unfortunately he never got it, HI. I do not know what you taught at college level, but, it is a shame that by that point adults cannot use correct spelling or grammar. When I started college here in the states, I had barely been in this country for a little over 8 years and I have to tell you my English and the use of it was pretty poor. On top of that, while in HS and in college my priorities were never on my English courses but in math, science and physics. It was not until I started working in industry, which I also did full time while in college, that I started to appreciate the significance of the written word and its ability to convey ideas properly. As time went on and I had to write technical papers myself, it became more and more significant and I become more and more versed in the use of what we call proper English in the States. I have been technical lead on numerous proposals and also had to evaluate many of them over the years. Nothing turned me off more than when I found incorrectly spelled words or poor grammar. I always felt that submitting such was a reflection not only on me, being the lead, but also on my company. Of course here on the internet almost anything goes. I would not have said anything about Lou's poor choice of words and grammar if he had not mentioned it himself. It was all in good fun from my perspective and I am sure from Lou's as well. 73 – Mike

Subject: RE: [AWA Group] DET1 es Mike

Having lived around many different ethnic groups in this great country of ours, having taught adults at a college level who were long past correcting their English and have finally realized that perfection for any of us is probably not available this side of the grave I am happy when I am spoken too, appreciate the effort no matter how difficult it is to understand and refrain ever from correcting unless someone is searching for the word. When traveling having learned some of my languages after I turned 50 and having learned others long ago and partly forgotten I sincerely hope folks will forgive me when I error as well. And I do, often. As for the concept we should l speak and write perfectly I aint never seen a reason to and hopefully never will. In fact perfect people are boring and often self absorbed. It is the Festus Hagans of life that keep it interesting. I have a very good friend who was unable to learn to read until computer equipped phnes came along. He is the same age as I. He is a plumber by profession and an electrician on the side. His

English reflects his up bringing in an non English speaking environment and he uses terms like LABtop to describe a computer BUT he is a genius as a craftsman and very smart on how to find out what he needs to know. He will wire your house faster then you can talk about it and the inspector will find nothing wrong and it will be to current code. He will fix your heating and do your plumbing also top drawer. He is in fact who folks call when no one can figure it out. He understands things. I have no idea how he knows but after 40 years of friendship I just accept it. He has no idea there are two Then/Thans . Heck he can't even swim however I would never stoop to correct him or his English. I seem to find more important things to do. Like finding new tubes and building new radios. The other? It is just foam. Blow it off and drink your beer. It isn't that big a deal. My cousin Martin Dolmetsch said it best the last time I was in his home in Metzingen Germany. He was comentng on my language skills as he doesn't speak or understand English. He said to me in German, Don, Your German is now perfect! I replied , No it is not, to which he said Es ist gud genug.(it is good enough) In my heart I said, Bless you Martin. May you live an extra day. It was a good reminder and one of life's lessons once again confirmed. Don't sweat the small stuff. Gotta quit now. The regen is running and no one listening.
donVe3LYX
BTW that is a wild looking tube. Hope it gets lit sometime soon.

13278. Might be spring fever. Need some info.

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-16 18:33:49 UTC
From: dulmagedon@...
Topic: 13278 Message: 13278

Spring arrived today.Tried to check into the OMRN with my Bomber ARC5 but no dice today. After breakfast I dusted of my old trade skills and fixed the brakes on the XYLs SUV. From there I moved to finishing a repair I started on the 63 Dodge 426 MW last winter (Larry has probably already been out cruising in the Falcon) As I worked I wondered about a Ham radio for the old car. Then I realized I have a good Heathkit Two-er. Does anyone know of that is period correct? I would much prefer a Tener but I have this one and it works well. It is even almost the same color as the car. I believe they come with 12volt PS function but I will have to look. Don't remember for sure. Yes I know it isnt our usual subject but I also know some of you will know for sure if twoer and tener production years included 1963. If so that will hold me till I find a 1929 Dodge. Then I can take my TNTs and Hartleys for a ride. Why a Dodge? Well my name is DOnDulmaGE ;>)
And should anyone want to trade a tener for a twoer I am up for it. I used to work a lot of 10M in the 1980s. Also spent about a half hour on the Meissner project early this morning. coil is done, alll four windings and the base board and tuning cap

Don –

The HW-30 is definitely period correct for 1963. However, I do not know who you will find locally on 2 meter AM. It does work off of 115V or an external supply. I have a pdf of the manual if you need it. It is about 1.5 megs in size. 73 – Mike

Thanks Mike. I have a friend (honestly I do;>) who has a twoer as well. The plan was we could work each other. I live on a ridge and he lives near Trenton Airport which is below me and about 12 miles away so I snagged the twoer in a deal and got us both the same rock but three years later nothing so i doubt it is going to happen and am sure he has not even ever plugged his in. (he also has an HRO60 in the same situation and it looks good. Very good in fact. So I gave up on the idea. I guess with a tener I could at least work some HF AM. Otherwise I am not nor was I never much interested in 2M so that is how I got it. I have tested it though and it works well. I can copy the local repeater too. Anyway t'was a thought. I'll put it on hold for the moment. If I need the manual I will send you a email Mike. I would have to go to a hi speed connection spot to do it.
Good show on taking the Falcon out Larry.

i don't have many pictures of my ride by itself but here it is. In the background by the hanging birdhouse you can see my ground mounted 20m vertical which has a been a great ant on 20M for me here. The new 80m vertical I just put up was in the grove of cedar trees just behind this. The black steel pole attached to the house used to hold my inverted L which the new 80m vertical replaced. I removed it a couple of weeks ago after affirmimg the new vertical was doing the job. The dragster is the car I crashed in about 2 weeks after this foto. Since it is retired I would like to out a rig in the 63 Dodge. What is the rig you have in the Falcon?
Oh We bought this car and resorted it as our Millennium project so the XYL calls it Milly. I use it quite a bit in good weather. I guess I need a vibsupply to run the twoer. I have one I use in the shack for some rigs but it is a bit big to go in with the twoer I think it is a GD-11 or something Heath made that is supposed to be used with it. I see them on Ebay from time to time. That would be a start however I would be a lot happier with a tenor. Any other suggestions for 1963 mobile HF Am or CW.? I was just getting into radio when this car was made and hadn't built my first crystal set although I did build a telegraph in the house, buzzers and all. I remember it was a brand new house in Arnprior and I got in trouble for string wires all through the upstairs. the old boy (Dad) allowed me one ops where I sent a message and he replied. (Dad had learned morse as a radio instructor during the war and he taught me.) Then I had to dismantle my "ontraption" as it was called and clean up the mess before I got anything to eat. Since I haven't missed many meals I obliged. That was about April 1963. I was 13. I remember because in the showroom at the Chrysler dealer in town was a car very much like my 1963 Dodge , Even the same colour. (not 426 MW though) Funny how you remember stuff from boyhood days.

Mike,

After this posting in this topic I shall close my membership for a week or so.I am waiting that long as one would for the propagation of a web site address throughout the web.

Hopefully when I sign back in I will receive daily text digests without html hot links to oblivion.

Yes, I am seeing the images of I go to the Yahoo groups "All my groups" and open AWA Group. I do not expect images to come with the daily digest. However, it s to bad they (Yahoo) still sends all the code for the image. They could at least post the word [image] and save the bandwidth,

You will hear from me in about a week 73's

Charles A. Days, WA1JFD in S. Dartmouth MA

The Postman left parcel in my mailbox today. Inside was the most unusual tube socket I have ever seen. Thank you Lou. I have been working on the Meissner anyway so I just continued on. Tube is all wired in and everything except the RF choke is installed. I made the choke tonight from a 1/2 hardwood dowel. I cut four circular grooves in the dowel evenly spaced and filled the grooves with no 28 enameled wire. I then sent it for a swim in the varnish pot. It is drying right now. I think everything is done once that is installed . Next I have to make a PSU for it. I am aiming for 160 volts under load maximum. I am pretty nervous about this build as it is an unusual design to me. Here is hoping. The split tuning coil is from one standpoint weird and yet I understand also the phrase Alles in Ordnung and what is behind it. An obsession with a balanced approach to design and appearance for one thing. Otherwise it probably doesn't make much difference. Anyway I am braced for the possibility it starts out a a dud. Hopefully it isn't too hard to sort out.

There are two of them, and I do have both. They are pretty simple really. The input drives an earphone type element which then is mechanically coupled to a carbon microphone. The carbon mike, through a battery, goes to a transformer to match the output, which goes to either an earphone or a speaker. It is a combination mechanical, electrical amplifier. This is the larger of the two and has two stages. The smaller one only has a single stage.73 - Mike

A one tube power oscillator using the German Meissner circuit. I bought an A408 tube out of Austria, Got a genuine European tube socket from Lou. The Meissner circuit is similar to the old Armstrong circuit except the tuning coil is split and the ticker is reversed to the Armstrong. Bill already has one up and running. Lou built an all British rig so I decided to do an all German rig that being my heritage from both Mom and Dad despite the anglicized current spelling of my name . The tube I have is 1924.

Thought you'd like to see a 1930's transmitter that I acquired several years ago and will be selling. She is a beauty! She's probably a replica built with original parts. It uses a 210 in the oscillator, I forget what the buffer uses, then it's geared up for the monster 860 tube. Go out on youtube.com and see how 860's love to glow bright hi hi. It came to me with no tubes. I did acquire an 860 so that would be available. I haven't figured out price yet. 73, Scott WA9WFA

I say! Seeing how the Queen is as German blooded as I am (Elizabeth Cobourg-Saxon (Windsor being a name only adopted by her family at the beginning of WW1 on advice from Parliament) I'll assume it came from the royal family and use it anyway. In reality It is a very short trip from Germany to England and not a stretch in anyway to think a Standard European tube socket which is right for the tube could not have come from England or Holland or France even anymore then a Canadian could not have used an American socket or visa versa back in the 1920s. I have crossed The Channel from the Continent to Harwich, England . Is a mere 55 minutes today. Probably a few hours back then by sail so I will live with it and appreciate having it. It is the right socket for the tube. ;>). So thank you still.
It is all done now and awaiting a smoke test. I always take a while to work up my nerve. And I am nervous about this one because the design is so different and solid info a bit scarce comparatively speaking. I have a plan B but am hoping I don't need to use it.
BTW I had the UV199 TX going Monday. It is not a strong rig but it works and that is enough.
No pics till it is working BTW. Das ist gebot.

Thinking about this some more makes me believe that there may have been some collaboration between the French and the British on this base configuration. They both had transmitters and receivers using R valves during WWI. The Brits had a lot of strange pinout configurations as did the Germans. I think by the very late teens and early 20s, most of Europe including the Germans standardized the majority of their tubes to the R valve pin configuration. 73 – Mike

Thanks Mike. i know even the European sites refer to it as a standard European socket (or sockel) so I suspect it is correct.
It passed the smoke test today but it doesn't run. I have to do some thinking now. Plate voltage is 131v keydown. Plate current 5.1ma , Heater voltage 4.33v, Grid neg -4.03V. Seems to me these are reasonable so usually if voltages are reasonable they run. I must have done something wrong but so far it looks right. Obviously it isnt or it would go. Tank tunes 10.50mhz. That may be too high for an old tube but somehow I doubt it however i will pad it to 40m. I may whip up an Armstrong coil assembly to see of it runs with that and if so work backwards. Won't make the MSN tonight I think as I will be late returning home. Have fun all.

Hello gang,

Well over a year ago, Lou (VE3AWA) asked if I wanted to take on a restoration of a Radio Engineering Laboratories (REL) Cat. #215 transmitter. I was unable to resist. He had acquired it from Harry (VE3GRO) several months prior, who had found it years earlier at a flea market or hamfest.

The 215 was one of several transmitters REL sold as kits in the late 1920's. It is a three-tube rig with a 227 oscillator (configurable as either a TNT or Hartley), a 224 buffer, and a 245 amplifier stage.

I have documented the restoration process in the attached pdf file. If for some reason the attachment isn't there, I will place a copy in the Files section.

As of last week, I had an operational transmitter and the time came to try a QSO.

It took a few attempts, but at my Apr. 18 sunset, Lou VE3AWA and I completed a contact, with Joe N3IBX and Steve VE7SL listening in. Lou was using his REL-175 and so this was a very special REL-REL QSO that we had planned for a long time.

73 all,

Steve KK7UV

GA All,
While running the 2A5 rig this PM for a bit, I did a lot of CQing. Previously the band had been pretty dead. I made one QSO in MD with 589 both ways. However, later I was looking over the RBN hits, which were quite a few due to all the CQing and see that a few of the RBN reports were: W8WTS-29db, K8AZ-42db, KM3T-34db, K1TTT-42db and VE2WU-33db. All were at 1847Z except VE2WU at 1858. Most of the other reports were at my usual levels....+/-10db to in the 20s. Anyone else notice anything 'flaky' on 40 this afternoon. Just wondering why the 'lil rig was so strong at a few spots....whatever the reason...I love it. The 2A5 was running probably abt 16 w/in and maybe 8 or so out and on the 80m Windom.

13312. Need Marconi information

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-21 22:21:22 UTC
From: JAMES HANLON
Topic: 13312 Message: 13312

Y'all,

Once again, I'm working on a talk for this summer's Albuquerque, NM Hamfest about the significant developments in amateur radio technology from 1895 to the present. I've found on the web a picture of a recreation of Marconi's first transmitter, vintage 1894, but I'm not sure I believe the diagram I've found associated with it. The diagram I have shows a battery and switch (key) connected in series across a single-winding coil. A capacitor comes off the top of the coil and is connected to the top side side of a spark gap. The other side of the coil is connected to the bottom side of the spark gap. The top of the spark gap is connected to a "plate" asking as an antenna, the lower side of the spark gap is connected to another "plate."

Elsewhere, on Wikipedia in particular, I read that the coil was actually a Ruhmkorff Coil. It is a two-winding transformer with a vibrating "interrupter" in series with the primary that pulses the primary current and thus produces high voltage pulses in the secondary. I'm pretty sure that the "coil" in that diagram would have to be a Ruhmkorff Coil.

As to the "capacitor" in the diagram, the description and picture of the first Marconi transmitter on Wikipedia does not mention a capacitor. While I can see that the LC circuit comprised of the Ruhmkorff secondary and the capacitor (connected in parallel when the spark gap breaks down) would form a tuned circuit and might oscillate depending upon the damping in the circuit, I do not think that Marconi initially employed any tuning in his first transmitter. I think he just connected the secondary of his Ruhmkorff transformer to the spark gap directly without any capacitor in series and "let her rip."

I've found another diagram of a Spark Gap Transmitter circuit that looks more believable. It has a Ruhmkorff coil with a battery, key, and interrupter in the primary. The secondary is connected across a "condenser" and the to the two ends of the condenser are connected to a spark gap in series with a coil. The coil is inductively coupled to an "oscillation coil" whose ends are connected to an antenna and ground. That's my understanding of what a single-gap spark transmitter would have been like in the 1910 +/- era when "tuning" was being used. The secondary of the Ruhmkorff coil would have charged the capacitor to the point where its voltage would break down the spark gap. The charged capacitor would then be connected across the inductance of the antenna coil primary. That LC circuit would have given anything from a single pulse to a rapidly decaying sinusoidal waveform at the resonant frequency of its LC combination, depending on the amount of resistance in the primary circuit, due to the spark gap resistance and to loading of the secondary circuit. That primary waveform would have excited a longer lasting, slower decaying oscillation in the resonant circuit formed by the antenna coil and the capacitance of the antenna. If they were both tuned to the same frequency, so much the better.

So, what I'd like to know from you folks is this. Am I likely right about the hook-up of the original Marconi Transmitter? And do I understand correctly how the 1910 transmitter worked?

Thanks,

Jim Hanlon, W8KGI

I checked and saw you were still ringing the bell on the RBN 7048-9 at 1945z. Went down to studio B , warmed up the 211 TNT just in time for the CW practice transmission.Went below to --46 and above but too little too late I guess. Band was still open as I could hear a few signals still but eventually it got quiet. Anytime you or anyone else wants to test , if I am home and see the note I will be there. If one of you is testing I will run one of the 211 rigs so you wont be straining to hear.

Hi Jim,

If there is a transcript of your talk, please share it here after the presentation. Lou

Am I likely right about the hook-up of the original Marconi Transmitter? And do I understand correctly how the 1910 transmitter worked?
Yes and yes.

I do not think that Marconi initially employed any tuning in his first transmitter. I think he just connected the secondary of his Ruhmkorff transformer to the spark gap directly without any capacitor in series and "let her rip."

Correct, as you see.

I have visited Villa Griffone, Marconi's home/museum. Up stairs in The Attic were displays including a reproduction as you see here. Being alone, I reached over and keyed the rig. Unfortunately, the battery was dead.

13317. Meissner A408 Tx runs

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-04-22 16:37:54 UTC
From: dulmagedon@...
Topic: 13317 Message: 13317

At about 11.25 last night it barked to life. It is not a real strong set. Hopefully that is just teething problems.
It seems very stable and the note is clean however i have had it on batteries only so far. The A408 tube does not run hot. Barely perceptable warmth actually. I got the tube or plate draw up to 8ma at 129volts. A lot of flogging to go before I duel with Lou's britsh set. Still it was a thrill to see it up and running. todays goal is to move it solidly into the 40m band and optimize the grid leak assembly. Will keep an ear around 7049 in case Bill gets playing.

Congrats Don. I know that feeling when one of these things produces that beautiful sound of oscillation...surely puts a smile on ya mug. My Meissner is for 160 only, so an additional pat-on-the-back for moving up into the 'hf' region. That ckt is somewhat of an odd bugger, but I found, at least on 160, that it is quite stable. The only in-stability I found was with antenna movement due to wind...which, as you know, sounds pretty neat if not too bad. Probably won't be on any today due to storms. Have fun.

Thanks Bill,
It is a odd deal to work with and pernickity but seems stable. I am in the try this thry that stage now trying to find the sweet spots some good some bad. It will be awhile I think before it hits the air. Found an original circuit but there are also many variations.

First a quick update on the A408. I cleaned up all the extra long test style wiring making it neat as possible and guess what? Those who have been there already know. It doesn't work now. Probably not enuf feedback would be my guess. But that is ok. This is a side project anyway so I set it aside and went to work on the old 45 TNT. It didn't like the #10 and I knew from sniffer tests the grid coil was low in freq. Dynamic tests give somewhat different results then static CGO tests so I now use the sniffer for setting grid coils. This is the set I first did the loop on so I did some before and after tests as well with it.
I remade the grid coil since it had some war wounds. It is now centered nicely around 7200 but will go all the way to 7290 (AM window) or 7050 for CW. if need be. Sniffer stays brightly lit the whole way. I would highly recommend the sniffer for setting grid coils. Anyway after I was done I tried the Loop mod again. Deafening. Amazing how getting the grid on track better also improved the modulation and power. I did all the set up with the Number 10 tube in place after I got it heading in the right direction. Enuf for today.

My 1st car, which was also the car in which I learned to drive, was a 1963 Dodge Dart, with 3 on the column.

> What is the rig you have in the Falcon?
>
The XMTR is an Elmac A-54H (807 modulated by a pair of 5881s) powered with a PE-103 dynamotor in the trunk. RCVR is Gonset Super-6 converter going into the Falcon AM BC radio. ANT Webster bandspanner. IIRC the radio stuff is about a decade older than the car. I Make the most QSOs on 75M AM, although the station will also work on 40, 20, 10 (and 11!) meters.

Thanks Larry, I often wondered how those converters to the car radio were.
Back when predriving teen I had a No 11 Wireless set for SWLing Since it had a seperate PSU for transmit and receive Dad let me install it in the trunk of the 1961 Dodge (rig and only the Rec Dynamotor)when we went on holidays to NC , some beach /camp ground down there. I remember the girls at the beach wanting to know why we didn't speak Eskimo since we were from Canada. I was worried about border crossing but Dad told me to take the rig made in 1939 by Canadian Marconi (I had 2 of them)as our border people could not ding me since it was Canadian made and clearly stated on the production tag. . His thought was it would keep me out of trouble when we were camping as I would be occupied. I was occupied but always in trouble since I entered this exciting world ;>). You don't see No 11s anymore. It is too bad as they were a super well built set. There is one in the Communications Museum in Kingston (And probably a couple in Mike's basement). The engine is in the dragster is from a 62 Valiant Signet 200. A 63 Dart would be nice to have even today. They are getting expensive! Last one I saw and it was very nice was sold for $17000 Can funds. A neighbour bought it but I don't see it anymore so he probably sold it.It came here from the Calisle show.
That s a real nice set up up you have. Must be a lot of fun to operate.
Thanks for the update and GD DX. Hope to copy you when your mobile sometime.

Well, maybe you guys are too young, or, Canuks used a different terminology. However, I vividly recall from my youth that whenever a group of us young hams saw a YL with beautiful proportions, it usually elicited a comment like "Wow, what a chassis" from one of us. Consequently in the ham vernacular it applies equally well. 73 - Mike

Well, maybe you guys are too young, or, Canuks used a different terminology. However, I vividly recall from my youth that whenever a group of us young hams saw a YL with beautiful proportions, it usually elicited a comment like “Wow, what a chassis” from one of us. Consequently in the ham vernacular it applies equally well. 73 – Mike Mike B. Feher, N4FS89 Arnold Blvd.Howell, NJ, 07731732-886-5960 From: AWAGroup@yahoogroups.com [mailto:AWAGroup@yahoogroups.com]

Thanks Lou, I am working towards that end. Once I got it running I quit for the day after I made sure it would go every time. I ran it off my 26 tube regens battery supply. I did at one point hook the antenna and ground to it. It still ran. I dont think it is very powerful but I think i could run this tube maybe 180 volts safely which might be enuf. I also have been practicing drawing Der Schwarzen Adler so I can draw it on the front panel and it will look right. If it works out I will go on the hunt for a 1920s German Key. I have moved my keying out of the rigs and into the PSUs on some of my rigs and will continue that practice from now on I think. It sounded nice on the monitor but that is probably due to it being on battery power. Anyway when I get to that point I will give you the first QSO. I did fire up the 210 in the TNT today on 7290. Got a response from Rheinbeck NY and we tried a couple of exchanges but conditions were against me at that power level. The 210 is a interesting tube. Similar in power to a hot 45 but a lot more suited to transmitter use. I didn't realize that before.

Here is a teaser. I have to try and make it pretty behind the panel. Hard for me. It is like painting the inside of an engine. (Why?) But I'll do my best. Here form follows function but sometimes a long way behind. Function is where my interest lies.

Ok it is now working not bad. It has a very nice note. Not much power though. u Just under a watt out I would think. Testing though indicates it should be heard if all is good. So i am tuned up on 3693kcs and would suggest + or - 3 when hunting for me as not all digital rxs read the same freq. Not will not be strong but very clean. I notice no chirp. I am on battery power only so will have to keep it short. So at whatever time we agree on I will send slow VVV VVV VVV de VE3LYX till I get a reply. I did some more research today O guess I really need a A134 tube but this is what I have so there we are.
If the closer stations can monitor as well it might be good. Ie NY state. And I did clean it up more today.

Here it is. Not much to look at I am afraid. Coil is the biggest item and took a lot of experimenting to arrive at this one. I tried a split tuning coil but wound up eventually with this one. And it took a lot of flogging as well. Interestingly for me anyway rig will run with no grid resistor but any reasonable value settles it down noticeably. Then it was a matter of sorting through to find the best trade off between good note and reasonable power.
This design despite some handicaps power wise would have no trouble meeting 1929 rules I suspect. Very clean from what I can tell here. I have to find what battery brand was hot in the 1920s in Germany and make facsimiles.
I also would like to build a proper set of 45 volt batteries. I ran this successfully as high as 170 volts and have no reason to think it won't run at 180 volts. It will not run at 280v though. Batteries shown which are dollar store D cells have run the tube for many hours so far and are still at good levels. This tube runs cold. You can barely perceive it has a heater even after an hour. I am sure it is warm inside but you would not know that. Probably a very good osc tube. I couldn't fix first production exactly. Some sights said 1924 but Radiomuseum shows first commercial use in 1926. I have to confess, I stole this tube. I have just under $40 Canadian including getting it here. I have seen them listed for many times that. It must have had my name on it. They must have found out I look like die letze Kaizer. Anyway there it is for what its worth.

Vielendank alle (Many thanks all)
Thanks Mike I will look forward to seeing those battery pictures. I have bought batteries in Germany but they were always Duracel. Hardly period correct. The Kaizer story is an interesting one. We were on a bus tour in Austria and Germany . Sound of Music Tour. At dinner in the Behr Hotel in Innisbruck a retired British Banker said to me "Donald, have you seen the large portrait in the Lobby? I hope it won't offend you but it looks very much like you." I hadn't so after dinner we went and looked. It did moustache, and all. It was dark so in the morning we went down and my wife shot a photo of me standing in front of it. Our bus driver Dragoon who spoke no english was standing watching this. I said to him as he watched, "Hast du mein bild gesehen?" (have you my picture seen?) He snapped his heels together and stood at attention. Montioning to one of the tour organizers to come. We asked who it was. The organizer asked him. "Das ist die letze Kaizer" (That is the last Kaiser) (Kaiser of Austria, Franz Joseph)he exclaimed and so for the next few hours I was enjoyed the fun.
Anyway enuf of that.
I had it on an antenna and did some on air testing. I have a spot down the road that if I can hear a lowpower rig I know from experience that it will get out enough for a qso. The BE rig was the one I discovered this on. It sounds very good to me. A very clean note. It is bothered by hand capacity but that is because mostly the old capacitor is fiber framed not metal however once tuned that is a non issue. Power is not big. it appears near as I can tell to be just under a watt. But that can be enouf in good conditions. It is an 80 meter rig and tunes 80 easily. In and around 3600kc to 3700kc seems to be its favourite spot. I had it on 3693 for most of yesterday and it seems to be a good spot. Free of traffic. Whether it has enough power to reach anyone on the list I don't know. However that is my biggest concern as otherwise it seems pretty good. Tube acts like a 00A to me. However I found German sites where it was used as detector or low level amp in receivers which is its original use however for output stage it was not used. Anyway it works and for now that is enough. However I am going to Europe in a month and will see of I can find any output tubes when I am there. I am going to NL but Radio and ham radio in particular is very big there with many museums etc. However I will not be paying hundreds of Euros for one. Das ist verboten!

Got 4 more tubes coming. 2 are RE134 tubes so we shall see how they work. Out of Finland (I can still taste the reindeer sandwhich Fin-Air served for supper pugh puagh puagh!) Was there on a stopover to Vienna coming and going. Saved believe it or not $750 each by taking that airline and route. Was well worth it and an interesting experience. Finland looks much like Northern Ontario to me. Would go again. The diet though would take me some time to get used to. Anyway a toast to more power!

Gentlemen, I recently became the owner of a Gross CW-25 transmitter and I am in serious need of information on it. Absent fromthe unit is any coil data. The current plan is to make up coils for 80 and 40 meters and possibly 20.

If there is anyone that has any direct data on CW-25 coils or can point me to where I might find it, I would trulyappreciate the input. Even close-up digital pix of any coils would be a help.

Thank you.

Roger/K1TG

Roger,
Congrats on getting the CW-25. Sure hope you can round up some coils. I vaguely remember that the attached pix are of some Gross coils that I sent to Scott, WA9WFA. Not positive they were Gross, but at the time thought they were. (Just looked at Coil 1 pix and see a faint 'GROSS' on a sticker). So take the pix with a grain of salt. You might be able to get some info from Scott.

Don, you lucky dog.

Why from Finland?

Country:Germany Brand: Telefunken Deutschland (TFK), (Gesellschaft für drahtlose Telegraphie Telefunken mbH
Tube type: Triode, vacuum Power/Output

Identical to RE134 = B409 = L413 = TB09 = DX804 = D9 = E422 = L414 = RO4309= KL71401 = LL413
Similar Tubes Normally replaceable-slightly different:
415L ; B85 ; BF804 ; DT6 ; E4 ; L316 ; LU4A ; RE134_(Ce)
Other class quality (otherwise equal):
RE134W
Heater different:
PM4 ; RE134S
Other base:
RE134t
First year 1927 Tube leaflet collection E.Erb Analysis by original leaflets
First Source (s) Sep.1927 : Funk Bastler 1927 Heft 39

Base Europe 4-Pin (A, 4A, B4, since 1914) (Codex=Eo)
Filament Vf 4 Volts / If 0.15 Ampere / Direct / Parallel, (AC/DC) /
Description Identical with following valves: Philips B409 / Valvo L413 and: Cossor 410P, Dario TB09, Geco ?, Mazda DX804, Mullard PM4, Radiofoto D9, Triotron E422, Tungsram L414, Vatea UX406, Visseaux RO4309, Klangfilm 71401. See: «Radios von gestern» page 242.

The brand I did not recognize but they are RE134 and another similar number. Even if they are not wirklich Deutschalnd gebauen they are the type. My 211s were built by Mrs Wong but thats awight. I have the A408 Valvo which is as good as it gets. However because it is a cold running tube I believe its ability to make power is limited although it does make a very good oscillator for the very same reason. Why Finland? I searched the Re134 number and found two sets. One showed sockets in the picture as well. Cost was $50.50 each which is a mere pitance for these type of tubes , perhaps because of the brand. My monthly fun budget is $100. So I am done for two months however I decided not to pass up the oppourtunity. This fellow (hansu)has many ancient tubes including your beloved Marconi Osram models. I know from being there that few Finlanders do not speak English. In fact when there I never met a single one who didn't although that could just be luck. So I figured if I had problems I could at least communicate. So when I saw Finland I had no qualms dealing with them. Also Europe has a international shipping deal which Finland also offered which is unbelievably inexpensive. Typically under $15 US funds to my door.
BTW thanks for the spec sheet.

Thanks Mike. That will help.
Lou, as near as I can tell it is just under 1 watt out. It is 80M and is tuned up right now on 3600kcs +or-
It loads well into the antenna. The standing wooden rod has the antenna connection at the top which is just clipped on. (I use remeber a long wire with this stuff and no grd. The rod gets it up and away from the RF dept which helps eliminate some normal troubles. The low power does concern me but the tube is pretty light. Reminds me of our 00A. Certainly less potential then a 201A for sure. I retested this morning and can hear it plainly a mile away. I have found that if I can hear a low power rig at this spot down the road I have always also been able to have a QSO with it. It is sort of my final test before trying and it was good there. Anyway I am in the middle of a busy day so far but am going to try for a few minutes now on 3600 since the band is open at the moment. If that doesn't work out ok as I know it is early and this is a very short warning but nothing to lose. It has its own sound so should be easy to follow.

That is fine Mike, I almost understood that too! Not an easy language to learn i think. But don't quit. I am paying attention.
Today while taking the XYL touring Antique Shops I came across a Link Radio Corp Test meter Unit Type 2552. At first I ignored it but went back for a second look. The manual was there and the booth owner said he had check and the meter responds on test with a battery. The manual had a correction notice printed the day after I was born! I was toast. A little wheeling and dealing and it came home. It has a very good field intensity meter complete with antenna so I fired up the BE and tried it. Works perfectly. The patch cable to Link specific equipment is missing and the speaker and test jacks but all else seems to be there . It is on a wooden case
and the two test leads are also there.
Also we were talking about GDOs awhile back. I got the Booton going again. Appears to be a faulty condensor.
However I built the FET one in the Aug 98 Old Timers Bulletin but changed the design to suit me. I used a bit different indicator circuit but basically a LED in series. It appeared to work but I had a bad poly cap tuning so ordered one and a lifetime supply from Argentina. It arrived last week and I installed it. It works pretty good tuning 80M and 40m which is all I need for now. How does the LED indicator work? Glad you asked. Pretty darn good to be honest. When resonance is found it goes out and pops right back on when you tune by. I am mounting it in a wooden tea box so it doesn't look too modern but it works pretty good I think. It has only one coil which tunes both bands.

I was just playing with it a half hour ago. Tuned up on 3560 +or-.
Yes I will be out tomorrow morning (Stirling Flea Market) and I might as well tell you, my 92 year old Dad is not good and could change QTH s permanently in the next 48 hours so I am working around that uncertainty. Some of you have been there and know. He could bounce back and live another 6 or 7 years like his brother but I don't know. His "oil pump" is trying to slow down. So we will assume he does get by this.
We will need good conditions to be sure. Tonight it was noisy. Although I really thought I heard a reply but perhaps it was just someone calling another VE3. The phone rang (my younger brother telling me about Dad) and I lost the moment. So we will watch for good conditions in low noise and I will give you a heads up. If it is ok for you we will go for it. Would be a thrill to pull it off. Not a lot of power.

Thank you Mike, Well he died this morning at 6AM. Too bad but its OK to. 92 is more then most ever get and he could still walk and could still talk radio even. He was tired of being here and doing nothing I think. My radio interest and probably the way i approach it and other things even in my craft with racing are due to his influence. His greatest achievement in his eyes was the design of the AVRO Arrow radios for Collins Radio (Canada Division). If I had a pic of that plane I would post it in his honour. His legacy to me was his saying "One thing we know for sure Don is if you don't try it it WON't work. "
He always encouraged me to try everything I thought of. And as you know I do. He graduated high school at 13 and won the Ontario Math Award. End of an era for sure.
Anyway I am Ok. He had had enough. I look like him except I was supersized ;<) so i better behave. It was his influence that got me into Ham Radio.

I desperately am looking for 4 British AR3 tubes for my W/T Set C Mk II receiver. They could be duds, just to fill the holes. I am attaching a photo (from the manual) of the set and a photo of the tube from the web. The tubes are really scarce due to the weird base. They were not made for long. Rod Burman has 2 good ones, he thinks, and wants about 100 pounds each. Two alone will not help. I asked him to see if he can find some duds as well, but have not yet heard back from him. I have had this set for about 5 years and still have not displayed it. Now, that I am retired and trying slowly to get things in order I am more motivated to complete some of these outstanding projects. Thanks & 73 - Mike

?VE3LYX:
Don, I have your father in my prayers and hope he has a speedy recovery. Even at 92 years old you still don't want to loose him. Hopefully he will get better soon.

Regarding a Hartley, TNT, or any self excited oscillator on 20M. Yes it can be done, but I'd be concerned about the Q of the antenna coil. I'd want it to be as robust and as efficient as possible. Your power output would be less than it would be on 80M ?or 40M.?

Lou, VE3AWA,
Regarding 211's made by Mr. and Mrs. Wong, I have experience using them as audio tubes in a BC-375 and they worked as good as those made by Mr. and Mrs. Jones. I believe the ones I used were the "Shuguang" brand, the one with the bird symbol on the glass envelope.?
Regarding how they would perform as self excited oscillators, I guess they would work as well as anything else. Give it a try and let us know if you can.?

Mod-U-Later,
? ? ? ? ? ? ? ? ? ? Joe Cro N3IBX

Well I went on to the Stirling Flea Market anyway as staying home wouldn't bring Dad back. So I was alone with my thoughts in a crowd. Was probably good. for me. Just got home. Did some dealing and came up with a box of earphones and operator headsets plus two of these. Probably paid too much but I haggled best I could and would only haggle for the whole box. Probably 5 complete sets of just earphones. Two are Trimm. Others are names I dont recognize. Just untangled all the wires and put each set in a freezer bag. One set of earphones has no wires and no diaphrams or caps. Over the next while I will test and see what I have. BTW I have two British tubes from the 40s. I will see what they are. Seems to me I bought them for a No 9 Canadian Wireless receiver.
I bought extras but then sold the set to a friend with a WW2 covered troop truck.

Thank you Joe for you comments. Dad had a good life and a long one. We are grateful for that.
BTW I have two 211 Shugang Self exciteds. A TNT and a Hartley. I run them about 1/2 throttle . I like them because they almost always get an answer. I have modulated the TNT one with a stand alone cathode modulator once. It seemed to work decent but never tried an AM QSO. I usually use one of them at least once a week.
Also yesterday I bought a model T Ford coil with hopes of building a small spark transmitter with a proper tuned circuit. This is not for on air of course but just educational for me so i may have to sneek into the old lab and borrow the farady room to test it.
The twenty meter deal thought for me was if it can be done well it would give the very real possibility of a pond hop even on low power and that would be fun. There are as some of you know a huge number of hams in NL very interested in any radio adventures. I also have a friend in Wales who is a retired ships sparks who has done a pond hop with me and the No 19 WS. He is relentless in scheduling so is usually eventually successful.
Never quits trying and won't let you either.
Here are my 211 rigs Joe. One is called Louis II because Lou inspired it.

Ferranti di make a lot of Audio transformers. I would sya the P and the S markings would confirm that it is an interstage transformer. I do not think they had "interstates" back then, HI. 73 - Mike

The horn mic works pretty well on the 45 hartely with the built in 01A cathode modulator. (3837kc)

Later checked through earphone pairs. Both Trimm phones work but a pair of Frost Fones don't however cord looks suspicious.so it may be minor.

model T coil worked after some minor flogging. Pumped it through the HD antenna tuner into a dummy load which it lights. Gotta figure out how to do this properly.

My younger brother was going through some of Dad's pictures cleaning out his stuff and came across this photo from the 1960s. It was taken inside Collins Radio of Canada, Burmondsey Rd plant where Dad was an Aircraft Radio Design Engineer in the late 1950s and early 1960s. The significance of the photo is it shows the Unholtz Dickie vibration machine or table against the left hand wall (Big round thing) Dad bought it when he was designing the radios for the AVRO ARROW because that fighter bomber plane was capable of over Mach2 despite its 1950s vintage. The machine has if memory serves me four 4-1000 tubes to power the shake. It was the only job it was ever used on and in the 1970s my brother and I went there and bought much of this equipment for the Lab Dad started with my Corporation. Certelecom Labs was the new name. (Now part of Nemko in Norway)
We also bought two environmental chambers although I don't know the one on the right was one of them or not. Dad said most of what we bought was used only on the Arrow project or when he designed the gas can radio for the Voodoo jets so was essentially like new. We had been there as kids many times when Dad had to work a Saturday morning or go in to shut down an overnite cycling test and record the results. Many of the engineers and techs knew us as little kids and when we went to pick up this stuff after my older brother (a skilled wheeler dealer) bought it about a dozen of the old guys who had worked with Dad came to the loading ramp to see how "Harry's boys" had turned out. We were quite surprised they remembered us and our names. I know Lou has been in the plant, at least in the library and perhaps others. We took the machine to our lab on Limebank road in Ottawa (Back side of Ottawa airport. It may still be there. My brother Dave still works there.

Dad liked working for Arthur Collins. He said Arthur told him at the beginning of the ARROW radio project, "Harry, make sure that is the best radio they have ever seen. Skimp on nothing!" donVe3LYX

Hi Don,

There are 2 ways to do it:

(1) Condenser (C) across spark coil secondary. Spark gap and inductor (L) in series with the series combination in parallel with the Condenser (which is also in parallel with spark coli secondary).

(2) Spark gap across spark coil secondary. Condenser (C) and inductor (L) in series with the series combination in parallel with the spark gap (which is also in parallel with spark coli secondary).

C and L determine (very broad) operating frequency, but keep in mind there won't be very much RF energy generated by the spark gap at wavelengths lower than 160M or so.

In either hookup the output can be taken from a link inductively coupled to the inductor (L), or for demonstration purposes, simply clip a "dummy load" light bulb across a couple of turns of L.

Wind a large secondary coil self-resonant at the same frequency as the LC combination, inductively couple it to L, and you've got yourself a Tesla coil. I made a couple Tesla coils soon after I retired (I always wanted to but had previously never found the time). One is spark-excited per above (but I used a 10KV oil burner xfmr for higher power) and the other is excited by an 833A Hartley oscillator. I wound one secondary coil that is removable. It has an octal plug in the base for the secondary ground connection. I tuned both the spark "job" and Hartley primary circuits to the self-resonant frequency of the secondary (it came out at approx 880 KHz, WCBS's frequency) and can use it with either. With the secondary removed from the spark-excited rig I can light a 25W 120V bulb clipped across 2 turns of the "primary" L for a spark rig demo.

I finally figured out what those insulators are. By 1930 a lot of people would have been throwing away wiring cleats as they upgraded their houses' electrical infrastructure. A pair of these would have sandwiched the two wires as they ran across your ceiling and screwed into your light fixture. They worked kinda like ladder-line spreaders for house wires in the pre-romex days. I'm sure this was obvious to people familiar with old houses, but it was news to me.
In keeping with the Great Depression, our predecessor was certainly resourceful. It's not a bad option for us if you are into period reconstruction and are tired of scrounging beehive insulators!

Thank you both. I got em and took a good look. If you could quad the 880 you would have it made! (3520). 25 w 120bulb is 50 ohms R too. On my low power tuner I have one permanently mounted that I can switch in or out. That is also how I tune the No 19 BTW. remove antenna , switch on dummy 25W and tune for max. touch nothing but just switch off dummy and plug in antenna. (I do not switch antenna but unplug it. That way I am not accidently sending dirt because I forgot to switch which I would. I know me.
But we are talking spark demos. I was able to light a 7.5 watt bulb about 1/2 way feeding it through by hb pi tuner. As bad as the circuit is, as was used, for being broadband interference generator there is still something here. Sort of an electromechanical noise gen. I am intrigued. I will build a proper demo model with a light bulb dummy but may explore the "just for curiosity" side of it. Elimination of the spark gap would be my first instinct. Its only purpose is to put sound on the signal before the days of BFOs or regens which come with one already. Probably foolishness but always interesting. I got the Ford coil for $5 so no big loss if it doesn't work. I saw a fellow building a Fedessen style AC rf generator using a multi pole stepping motor. Since Fedessen went to college in a nearby village west of me (Port Hope Ontario) that intriqued me too. Anyway lots of obstacles and perhaps impossible but interesting too. Larry I liked your comment about building the Tesla coils after you retired and finally had time to do that. I had one of those deals. It was 6 snowmobile carbs on a self made manifold on a slant six which is how and why the dragster still sporting that engine came to be. It worked from the git go and I used it for two years like that. I waited what seemed like a lifetime to build it and try it. It was eventually shown on TV on the GearZ show. However we are talking radios even though tuned length , resonance, speed of traveling wave and standing waves all came into the design of that induction system. I am easily sidetracked I guess.
Thanks again , both of you.

For some
reason my comments didn't make
it through. Here's what I had said in my reply to
Don:

There are 2 ways to do it:

(1) Condenser (C) across spark coil secondary. Spark
gap and
inductor (L) in series with the series combination
in parallel
with the Condenser (which is also in parallel with
spark coli

secondary).

(2) Spark gap across spark coil secondary. Condenser (C) and
inductor (L) in series with the series combination in parallel
with the spark gap (which is also in parallel with spark coli
secondary).

C and L determine (very broad) operating frequency, but keep in
mind there won't be very much RF energy generated by the spark
gap at wavelengths lower than 160M or so.

In either hookup the output can be taken from a link inductively
coupled to the inductor (L), or for demonstration purposes,
simply clip a "dummy load" light bulb across a couple of turns
of L.

Wind a large secondary coil self-resonant at the same frequency
as the LC combination, inductively couple it to L, and you've
got yourself a Tesla coil. I made a couple Tesla coils soon
after I retired (I always wanted to but had previously never
found the time). One is spark-excited per above (but I used a
10KV oil burner xfmr for higher power) and the other is excited
by an 833A Hartley oscillator. I wound one secondary coil that
is removable. It has an octal plug in the base for the secondary
ground connection. I tuned both the spark "job" and Hartley
primary circuits to the self-resonant frequency of the secondary
(it came out at approx 880 KHz, WCBS's frequency) and can use it
with either. With the secondary removed from the spark-excited
rig I can light a 25W 120V bulb clipped across 2 turns of the
"primary" L for a spark rig demo.

It's a lot more than that - the spark gap is your oscillator; that's
what's generating the RF. (I suppose a small amount is generated by the
sparking of the interrupter on the primary, but the lion's share comes
from the spark gap in the secondary circuit.) You can't eliminate the
spark gap and still have a transmitter, unless you go to a completely
different technology (Poulsen arc, vacuum tube oscillator, alternator, etc.)

> I got the Ford coil for $5 so no big loss if it doesn't work. I saw a
> fellow building a Fedessen style AC rf generator using a multi pole

The alternators, on the other hand, generate RF by themselves. They're
just a high-frequency AC machine. But I don't think they can get up to
MF, let alone HF. You run into physical limitations with the number of
poles and rotation speed.

I have been playing away and I see you are correct. The spark gap is the oscillator. I was thinking it was the noise EMI source but I can see after this evening I was wrong. I eliminated the spark gap by returning the low side of the secondary the same as we do in a tank in some of our transmitters. The dirt in the signal was the same. Probably a huge amount of it coming from the buzzer or vibrator. It should be enclosed in a grounded metal can. I don't know how far I will go with this as I am pretty well satisfied it was / is a bad idea. Ignitions system themselves is something I am very familiar with. I ran a specialty tune up shop in the 70s and still have two automotive oscilloscopes. Used to do demos for KAL Equipment on a contract basis in the 1980s.(it paid very well thank you ;<) I should hook it up to the Ford coil project so I can see what is really happening except I feel my interest in it waning already. I think I will just make a demo model of the second generation style used back then loading into a dummy light bulb for display and call it a day.
Anyway on another front my 211 hartley appears to tune up to 20M OK. I have it up on 14053 at the moment but am nervous. I need to make absolutely sure that is where I am for sure although all checks would indicate that is so. Sig sounds similar to how it is on 40M so would work ok. Man I wish there were other hams around. It would make things so much easier if someone was near who could double check and such. I have hams around but they have no interest in hb, tubes or CW or experimenting.

From: Mike Feher
Topic: 13412 Message: 13412

About a week ago I mentioned that I added a new bug to my collection. I received it today. As it turns out, up to this point only two of these were known to exist. Now there are three. This company was only in existence for a few years from the mid to late teens. Vibroplex at that time bought them along with some of their patents. Rather than attach pictures that take up a lot of space, I am including a URL that has 4 photos of the bug. The URL is about 4 megs, so, if you have a slow connection, you may not want to try it.

From: Eric NO3M
Topic: 13414 Message: 13414
Attachments: 1 described; binary payloads are missing from this source WARC

Anyone have any information about Decker coils, particularly years produced?

Just picked this one up and using it in a 160M 203A MOPA.

Thanks
73 - Eric NO3M

Eric –

I have never heard of Decker. The pin configuration is almost like the BC-610 coil configuration with some slight spacing differences. 73 – Mike

From: Eric NO3M
Topic: 13414 Message: 13416

Yes, the banana jacks reminded me of the B&W BC-610 coils also. I use a 2.0 - 3.5 BC-610 coil in my 1930s 160M MOPA; I have never been able to find a 160M BC-610 coil. I assume guys that have them don't tend to part with them. The pin spacing on BC-610s is uniform, this coil spaces the output link and center tap pins closer together.

I did a fair amount of research on the 'net, both Google and going through the Advertiser indices in the QST archives. Absolutely nothing on Decker coils. While I didn't go through every month, I pulled up the advertisers list for Jan from 1925 to 1959, figuring they must have advertised in QST at some point, as the box clearly suggests this coil was intended for Amateur band (160M) use.

Hopefully someone will have a fragment of info.

Steve -

The bug is actually in pretty good condition considering it is 100 years old. It also seems to work rather well. Consequently, I am just going to leave it the way it is. Since there are only three in the world, I doubt if it would hurt its value either way, however, unless a key in my collection is in real bad shape, I prefer to leave it looking old rather than some who make them look like they were just made, HI. 73 - Mike

From: dulmagedon@...
Topic: 13430 Message: 13430

As you know I had trouble with my Booton GDO. It has been behaving recently however i need something around so I took a circuit i found in an old Aug 98 Olt Timer AWA bulletin and addapted the cricuit to my purpose and a bit of redesign too. It uses an FET MPS102 or equivalent , an LED for indicating
and is faily broad in tuning covering both 80m and 40m on one coil BUT it is quick reliable and handy.
I put it on my Hamshack website since it is SS and not tubed but here is a link to my pictures and it is the bottom two pics. A schematic and a picture. I called lt Little GDO. (make a good song to sing at a Hamfest ;>)
The circuit is not exotic nor does it pretend to be anything but practical. The LED is in series with the battery supply but when the resonant point is found the circuit gets confused and the light winks out. Crude?perhaps but it works and is very definate and repeatable which is always good to my way of thinking. I made a box for it yesterday from an old 2x4 and some masonite . i have used it several times in te last few days. it is an easy build and works. Values are such that anything close will work. If I use it with my digital rx I can find the resonat point then find the osc alone on the digital rx and get an actual fairl accurate reading. it is actually easier to use then the big one and a bit more accurate as well. The indication is definate. . light goes out on resonance and pops right back on when not resonant. So if you don't have one already and need something cheap easy and relieble it might be the ticket. I built it on a Rs project board and the coil is made on an inside roll from an old Fax paper roll.

Very obviously. Three things obvious right off are: one is the exhaust tip is totally wrong, two there is only a single filament, and three, the method of plate attachment. I am sure I could find others I am sure if I spent more time on it. It is possible it is still old, but, I kind of doubt it. About 40 years ago Jerry Tyne told me people used to make them using light bulbs from a model T for a filament. 73 - Mike

While what Larry says is correct, the insulation was rubber, on some, which usually cracked over the years and people replaced them. 73 - Mike

I'm certainly no expert on stuff that old, but the insulation on the grid and plate leads looks too modern and in way too good condition to be original. A know this could have been changed, but my money's on repro.

With Dad's passing we have heard from folks all around the world who knew him and worked with him. One place I knew nothing about was a Collins web site for the Canadian division run by Jack VE3FAE. If you don't know Collins Radio of Canada was the only Collins facility outside of the USA and was operated from the 1950s till the 1990 even though Rockwell bought the company about 1974. My brother gave the guild a heads up on Dads passing and I have had two emails from them since. There are a lot of radio links there as well plus historical articles about Collins and ART C himself who occasionally made his presence known. There was a short note about Dad and his development and bringing to production the AN/ARC552 UHF Transceiver. Many folks here I knew. A few are still with us. Obviously that interested me but there is also a wealth of links to other articles and sites and some history on Collins gear including ham gear and some general radio history. There is even a link to Lou's old work place's famous radio museum. I know several of you have vintage Collins stuff, military or otherwise so here it is, www.antiquehistory.net http://www.antiqueshistory.net/Collins. I am away at the http://www.antiquehistory.net/Collins/Collins-Canada-Links.htmFuneral for two days. CUL donVe3LYX

Hi Mike,Re Cedar Rapids plant' Dad used to have to fly to Cedar Rapids every month or so. At first Arthur and Collins had this old twin tail Beechcraft and they would pick Dad up at Malton (Now Pearson) . That was back when you could go on the observation deck and watch the planes leave. We were always excited when he got back but he was usually very tired. He used to tell us the old beechcraft shook so bad his teeth were still rattling. About the time I was 5 they started flying them on Commercial airlines instead. He was much happier. However I remember one trip out was on an Electra and they had been having teething problems. One had lost a prop blade into the cabin in Toronto so I remember being concerned about that even at that young age as i had seen the pic of it on the front page of the Toronto Star. Then they sent him on an airline that flew Viscounts and all was well.
I am surprised at the response from the old Collins employee groups. Even though he left Collins in 1962 as late as just a couple of hours ago I got a note from one who worked in the same department after Dad and knew his tech (Every engineer had his own personal tech who always worked with him.) They were and still are a tight knit bunch. Anyway, end of an era for me.
At the funeral I met the son of one of Dad's students from WW2 No 1 Wireless School RCAF days. He and Dad had reconnected about 15 or 20 years ago when they bumped into each other. His Dad has passed already but he said he still had one of his Dads Collins receivers. (his Dad was a ham) He told me to come see him and it in person. I think i better.
Don

;<) I better go practice it on my fiddle! If we could get a Clarinet player (Clarinet and violin go very together well both being products of a tree as are guitars.) on the melody and Larry on bass we would have it made!
All that aside it is a very handy little piece of shack gear for quick checks. Not at all sorry I built it. I am in probably less than $5. It took about a 1/2 - 3/4 of an hour to make.

13457. 20m ops

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-05-08 02:34:25 UTC
From: dulmagedon@...
Topic: 13457 Message: 13457

Welcome Charles.
Earlier in the week we were talking about 20m ops a bit or at least Lou and I were wondering out loud. I dug out my old QSl cards from my early Cw days and went through to see if I did much 20m CW ops. Back then I operated under my first call VE3LYU. I used a Viking II CDC model with a Viking VFO for ops and listened on a Radio Shack DX 200 (Which is a rx I still wouldn't mind having again.) Most of my 20m Cw ops were in and around 14040 to 14045mcs. That is typical for me to stay more or less in one spot moving only enouf to avoid QRMing someone. I still op that way today. I have spent the last few days when home listening on 20M under 14100khz.. I may whip up a quick 1930s style 6l6 rig to test the waters before going all the way with a 1929 style rig. I want the final rig to be a good stable design.
BTW How did my call get changed? I don't know if i ever told you folks the tail but I operated for over a year as VE3LYU. even had 1000 QSL card made plus the usual stuff. One night I called CQ de VE3LYU and was answered by VE3LYU. We were both a built ticked someone was using our call but once cooler heads prevailed I said i would go to the ministry and find out what was up. Turns out we wrote our exam and code test the same day at the same faciiity and due to a clerical error had both been issued the same call. VE3LYU. I had been quite active but he had not been on that much till about then. We had the presence of mind to send each other a QSL card , Ve3LYU de Ve3LYU and I had it in my big mitt just a few minutes ago. He was Active Duty Military and i was not so the inspector gave him the call and gave me VE3LYX instead. I just chucked the remaining VE3LYU QSL cards a couple of months back. I had thought when he no longer needed it would revert back to me if i wanted it or so I hoped but when Derick became a silent key they reissued it to someone near Newmarket and I have worked him sort of (in a round table on 80M AM) since.
donVe3LYX.

I made and used a sloper on 80m back at the old QTH for several years. It was easy to do and seemed to load fine. I see quite a few QSL cards I got with it back in the day. 1981 and 82 I ran it mostly but right through to 86. Seemed OK, don't remember any issues but as you may or may not have noticed I don't have any dipoles now.

GM Lou,

I've used them routinely for backpacking/mountaintop operations. In such use I had typically been on the higher bands (15/17/20/30) and was also usually able to hang one end at least 20 feet high using a telescoping crappie pole where no trees were available. However, you are probably wondering about lowband (160-80-40) operation with the wires relatively close to ground?

13465. Tower & Inverted Vee -

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-05-09 22:32:17 UTC
From: Mike Feher
Topic: 13465 Message: 13465

For years people on here and on the air have been wanting to see pictures of my HF antenna setup before and after the storm. I put the tower up in November of '95 all by myself, with then my 18 year old son being the ground crew. My wife was too scared to even watch me up there. Anyway, it stayed intact for exactly 17 years. I built it to last. I had a pulley on top to lower the Vee in case something ever happened and nothing did. Low and behold along came Sandy at the end of October through early November, and, it still was fine. Then less than a week later we got a terrible north eastern where the rain coming down was ice. Tree limbs were already weakened by Sandy, and now ice laden a lot of them came down. Well, one tree on the edge of my property line in the front yard came smashing down in the middle of the night landing on the leg of the Vee that was supported by a tree close to the street edge, and then there was a big bang. You would think that that #6 solid copper wire would break, or the heavy parachute type cord supporting it to the tree, no, it had to pull the top 25 feet of the tower down right where the top set of guy wires were. Regardless, one of my landscaping guys last summer climbed the tower, even without a belt, and placed the antenna where it is now. BTW, they did take the dangling top section down from the top of my family room back in 2013. OK, by now I am sure you are bored. If you would like to get more bored, check out the photos in this link. 73 - Mike

Subject: [AWA Group] Tower & Inverted Vee -

For years people on here and on the air have been wanting to see pictures of my HF antenna setup before and after the storm. I put the tower up in November of '95 all by myself, with then my 18 year old son being the ground crew. My wife was too scared to even watch me up there. Anyway, it stayed intact for exactly 17 years. I built it to last. I had a pulley on top to lower the Vee in case something ever happened and nothing did. Low and behold along came Sandy at the end of October through early November, and, it still was fine. Then less than a week later we got a terrible north eastern where the rain coming down was ice. Tree limbs were already weakened by Sandy, and now ice laden a lot of them came down. Well, one tree on the edge of my property line in the front yard came smashing down in the middle of the night landing on the leg of the Vee that was supported by a tree close to the street edge, and then there was a big bang. You would think that that #6 solid copper wire would break, or the heavy parachute type cord supporting it to the tree, no, it had to pull the top 25 feet of the tower down right where the top set of guy wires were. Regardless, one of my landscaping guys last summer climbed the tower, even without a belt, and placed the antenna where it is now. BTW, they did take the dangling top section down from the top of my family room back in 2013. OK, by now I am sure you are bored. If you would like to get more bored, check out the photos in this link. 73 - Mike

Lou, I know nothing. I threw out my log sheets long ago. Being in the competition at a competitive level was the farthest thing from my mind. I keep a log and summit them only because I know it is important to the organizer to know some folks are participating. I wasn't trying to win or anything. I do thoroughly enjoy AM as a mode though and at that time of the year when band conditions are decent I am on AM at least once everyday sometime several times. I check The AM Window even now everyday because I really enjoy it. All I can say is I did spend a lot of time at it and used all three AM rigs, My ARC 5 80m, My Dixie60 and my current favourite the modded No 19 WS which has proved to be the most effective AM rig I own. I don't normaly run a lot of power unless on the DX60 with my homebrew amp (which is only 150W anyway) but normally am under 20 Watts output. I am surprised to say the least and As Larry says probably just lucky. Maybe no one else sent in their logs. I don't know. I know I had a lot more AM contacts that contest then I ever had in the BK or Linc Cundal events. I am pleased but surprised. And prefer just to quietly enjoy it. I am an old SSB Dxer so I am used to busting pileups and getting on and out quickly and am not much of a conversationalist so maybe that helps. I dont know. All I know is I love operating AM on old military gear and it was a fun weekend.

That's just it, Don. I'm not out to "win," either, but I have plaques on my wall for getting the high score in 2011, 2013, and 2015. I was one of a very few that sent in their log. I purposely didn't operate with my own callsign for 3 reasons: 1.) I was given the opportunity to activate W2AN on 75M, the most active band, so every opportunity I had to get on the air during the event I operated as W2AN, 2.) I wanted to see someone else take the "prize," and 3.) I don't have any more wall space for plaques!

Here is all I have from that event. The XYL took her camera to the downstairs shack and took a photo of me so she could remember who she was married to. I stayed up long after Larry hit the sack. I remember him signing out quite tired. This photo is from that event. No 19 WS I am tuning and you can see the Dixie60 and its deaf cousin HR10B to the left. donVE3LYX

Well you did a fine job with the W2AN. I know it must have been tiring.
For me , just making the contact is enough. I never used to send in logs (even when SSb Dxing) until AWA sight asked specifically for them and the reason seemed reasonable.
Like I said I really enjoyed it just for the fun as with the CW events as well. Is fun making a QSO with folks you already know from here or another website. In a busy world all we need is a good excuse to do it. These events provide that I think. The contest thing is to me incidental.

Hardware stores sell #10, #12, and #14 solid hookup wire. Just strip off the insulation and voila! bus wire. Of course, you'll have to tin it yourself, but it shouldn't be too hard. I once made a die with square holes of graduated size and drew #10 wire down to #12 square bus wire. Worked fine, last a long time.

I buy a small roll of 12/2 house wire. (25ft) Inside is a bare #12 ground wire, a 25 ft length of back insulated solid #12 an a matching white wire. To remove the sheath holding them all together just cut it with a sharpe knife and pull it apart. The bare works great for Busing, The black works great for self supporting coils and antenna outlinks and the white works good for the same in projects that are not pre 1930s and are not in open view. last I bought was about a week and a half ago.

A foggy morning coffee musing.

Does anyone know the origin of how "vernier" came to be misused with ham radio parts?

I routinely see things like this.

Note there is no vernier scale, so why would a manufacturer call this a 'vernier dial'.

My introduction to 'vernier' came with calipers and theodolites.

It seems at some point 'vernier' became synonymous with 'reduction drive'?

Steve, I think it just might be shorthand gone wrong. Vernier dial attached to a reduction drive becomes a "vernier. " Dial then becomes just a knob and the assembly is still a "vernier."

Some people call digital calipers "verniers" or dial calipers!

Steve -

Some "Verniers" actually did have a small band of divisions on the stationary part, especially in some of the early test equipment. This of course as you know allowed for extrapolation of a more accurate reading. I have never thought about it before. While the drive that you show does not have a Vernier scale, Some of the early dials like the National velvet style also had a segment of divisions on the fixed part. Such as this, and could be called a true "Vernier".

I guess the name then just stuck to any planetary drive, even if it did not have the second scale. 73 - Mike

YS...u need a holiday.

A foggy morning coffee musing.

Does anyone know the origin of how "vernier" came to be misused with ham radio parts?

I routinely see things like this.

Note there is no vernier scale, so why would a manufacturer call this a 'vernier dial'.

My introduction to 'vernier' came with calipers and theodolites.

It seems at some point 'vernier' became synonymous with 'reduction drive'?

It is a foggy morning here, too. The term Vernier was used in early radio circles differently than by machinists obtaining accurate measurements with calipers of the day. In radio the term was use more often to describe reduction tuning where five turns of a dial would cause one full term of the adjustable element. I just happened to have a 1923 Radio News magazine sitting here and in just a minute or two easily found the term Vernier used a dozen times when describing reduction tuning. So I guess you can name the marketing departments all jumping on the band wagon to supply the latest fad in the fad filled world of early radio.

The 1938 ARRL Handbook's catalog section shows National Type NW and Type N dials. Both have reduction drives and true "verniers" that are a type of dial index that allows accurate interpolation between graduation marks on the dial. The Type NW dial has a peripheral friction drive while the Type N dial has a planetary drive that National trade marked as a "Velvet Vernier" drive. Since the Type N dial has both the vernier dial index and the planetary reduction drive combined in the same device, and is named "Velvet Vernier" it is easy see how thereafter, just about all other dials with reduction drives came be called verniers. Even the National Type A dial, which has the planetary drive but has no vernier index is called a "Velvet Vernier" dial in the National ads.

Steve -

Well, you got a lot of answers. Seems some do not read previous posts and just repeat the same info. Just wanted to mention that I too worked with theodolites. My very first week of college I took a job with Traveler's Research Center back in September of '65. We were making atmospheric diffusion measurement testing. We used to send up helium filled real large balloons that had a light attached to the bottom. We followed, and recorded the path of the balloons using theodolites. I did this for about six months before starting to work for a transformer manufacturing company. Since someone had to pay for my college education and there were no other volunteers I had to do it full time throughout. 73 - Mike

13496. Early transmitter grid leaks

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-05-14 19:12:38 UTC
From: Andrew Flowers
Topic: 13496 Message: 13496

Here's a technological history question that some of you folks may be able to answer for me:

What kind of resistors did people use for grid biasing in CW transmitters during and in the following years after WWI and who made them?

Most of the schematics I've seen use the familiar grid-leak resistor in parallel with a capacitor (or a resistor-plus-RFC in parallel with the tank coil) for bias, but I'm struggling to understand what components were actually available for the leak resistor. The RCA UP-1718 and UP-1719 (forgive me if I've botched the model numbers--I'm away from the house and trying to do this from memory) were specifically designed for biasing the UV-202 and UV-203 transmitting circuits. The RCA parts are large (5 inches or longer) tubular wire-wound affairs. Around 1924 I start seeing adds in the radio magazines for the non-inductive resistances. I'm guessing that the wire-wound resistors started causing problems as people moved to the short waves and there was a market for a different technology.

Surley RCA wasn't the only game in town for grid resistors, but it found it surprisingly hard to locate resistors manufactured circa 1920-23 with values large enough for a TX grid leak (say, 5-20K). Maybe I'm not looking in the right places or for the right things. Maybe there wasn't much of a market for resistors in the range....that's what I'm trying to understand.

So, what kind of bias resistors did hams use in their CW oscillators in the early 20's and who made them? I see the "non-inductive" resistors (e.g., Crescent Lavite) being marketed in 1924, and I wonder if this had something to do with problems of stray reactance with the wire wound technology. Anyway, I'm interested to hear from people more knowledgable on the subject!

Thanks,
Andy K0SM/2

Hi Lou, I found, in general, that they need extra turns on the tickler windings. The original SW-3 forms used aMica-filled Phenolic called R-39. The R-39 coils have a higher Q. I bought and used a number of themfrom Mr. Fred when he was alive. If memory serves me, he said the fabric base was Canvas.

Noted. Tks 1TG...

Hi Lou,
I found, in general, that they need extra turns on the tickler windings. The original SW-3 forms used a
Mica-filled Phenolic called R-39. The R-39 coils have a higher Q. I bought and used a number of them
from Mr. Fred when he was alive. If memory serves me, he said the fabric base was Canvas.

Roger.

If from France to England maybe on a real good day with an awful lot of luck as it isnt very far.(maybe 35 miles or so. We could ry St Pierre Island to Nova Scotia which would be France to Canada and also not far. However I am from experience somewhat suspicious of some such claims. I have several rigs in the 1 watt range and many of them have never had a contact.
As far as using a regen circuit, there is no significant difference between a transmitter circuit and a regen circuit other then earphones and plate voltage applied. I have built a regen with a switch to bypass resistor, regen pot and phones which allowed ti to transmit It was hartley based which is the easiest. I did get a report on that one so it can be done. My birdhouse regen transmits too simply by going from 68 volts to 120 volts so that I can handle. However I am very suspicious of claims by QRPers who worked 1500 miles+ on 500ma never mind 50 miles on 3ma. My experience has been from both QTHs that I need about 3 watts to do anything. At least on 40m and 80M. If anyone else has the magic secret please share it. And that means actually done it not "know how it should be done."
I have been going through some of my homebrew stuff scrapping some that even thoigh they worked did not meet a reasonable performance level I want or are too wonky. My 45 TNt is one that is going to become something else and I am just not thrilled with its manners even though it has worked for a lot of years I think I can do better. Today i have fitted the 210 tbe into one of my orange craterigs and want to see how it erfoms on 40m (7063 kcs i my tune up) I will be trying it this morning as soon as 40m becomes viable. (9:30 to10:00 after 80M crapes out) Any ears would be appreciated.
I do pretty well on low power as the AWA event was run almost exclusively with the No 19 which is not a powerful rig in any way for AM ops so moderate power I am used to using. However I am open to any ways to make successful QSOs at Low power. Interesting subject.
I keep thinking was that Hercule Perroux the fictional Belgium detective? ;<)

Lou,
I find nothing too surprising about communicating with a few mW input. When I worked on you on 40m with my Hartley at around 4W input I think you said I was peaking at S8. If you figure a stingy 5dB/S-unit on your meter that means I would be S2 with a whopping 4 mW input (-30dB). That may or may not be above your noise floor, but on 40m during the day it stands a good chance that it is, and it almost certainly was in the gentrified countryside of 1920's England. We're about 150 miles apart.
I when I get to that point, I was thinking of running the 202 filaments on slightly lower voltage as a way of staying under the BK power limit while preserving the remaining tube life. With pure tungsten filaments there's no cathode poisoning and there's no rare-earth doping that needs to constantly be boiled up by the heat. So I understand...

Don,

GM.

However I am from experience somewhat suspicious of some such claims. I have several rigs in the 1 watt range and many of them have never had a contact. I have a 50* miliW 80 rig. I was 329 into Maine.

*True measurement

GM Andy,

I find nothing too surprising about communicating with a few mW input. ......We're about 150 miles apart. My AW-2 is on the bench now. I'll key both the antenna and B- to see if that aspect is workable. Let you know.

I was thinking of running the 202 filaments on slightly lower voltage as a way of staying under the BK power limit ..... You've mentioned several means of staying within the Legal Limit, but not the most used. That is, reducing the aerial link coupling... or have I missed something?

Beautiful day.

Lou

Hi,

I have not been following this entire thread (nor any for a while) but it caught my eye just now. Ultra low power contacts are real. It has been done. It can be done.

Back in 2004/2005, N2XE was running some very low power beacon experiments on 160 meters. I was able to copy his beacon at a distance of 351 miles while it was running 250 microwatts output into a simple inverted L antenna. I was using only a simple inverted V at the time. W4ZV was able to hear it at 548 miles using a Beverage antenna.

I am uncertain of all the details but while reviewing briefly for this post I found a report that W4ZV copied the N2XE beacon on 80 meters at 40 microwatts. For all I know there may have been even greater achievements in the series of tests. I don't have time to review in depth right now. A thorough search of the TopBand list archives should turn up more facts.

But have any of you, by that I mean us actually done it? built a under a att rig nd worked or are we just repeating what we have heard, think or read.
4 Watts I have no trouble with and have some experience with. .003W? I am very skeptical. The hlf would only be down X DB stuff doesnt touch me. I know only too well when a extra bit of punch would be the difference between a QSO and no QSO. Been there too many times. Noise and atmospheric conditions don't know about mathematics. And you have to be above the noise which can be a problem these days. Joe and I talked once about putting our GDOs on the air just to see. And even we optimists knew it would be very iffy. So instead of I have been told or I think or B =9 over 7 etc I propose we actually build some flea power stuff and try it. If it works I may put a VFO on my SUV's key fob and add a tuned areial and work some DX. Heck we can sometimes barely hear each other on the MSN with 100 watts + . The UV 199 has that kind of miniscule power. I KNOW no one is going to hear it so I haven't bothered. I have a micronaut sort of I built with well over a watt out on 3.56kcs. It has yet to make a contact after a year of trying. As I said experience has simply not convinced my these exceptional deals can work. However nothing would be more fun if it could be pulled off. So if anyone actually as one under a watt even Give us a freq and we will see what we can hear. I am curious but very skeptical.

Don, based on the Reverse Beacon Network my 40 mtr 1 watt transmitter is being heard over most of the US. See https://3.bp.blogspot.com/-1uu20oIqwuU/VvOlx0n03TI/AAAAAAAAA8Y/jifEwYmdQiEBKVnpMRtVUYdM5r6NqXcSQ/s1600/3S4x2RevBeaconNetwk.JPG https://3.bp.blogspot.com/-1uu20oIqwuU/VvOlx0n03TI/AAAAAAAAA8Y/jifEwYmdQiEBKVnpMRtVUYdM5r6NqXcSQ/s1600/3S4x2RevBeaconNetwk.JPG and http://w0vlz.blogspot.com/search/label/3S4%20QRP%20Transmitter http://w0vlz.blogspot.com/search/label/3S4%20QRP%20Transmitter I got a 559 from W3BBO in Eric, PA.

My antenna is nothing to write home about... 90' endfed wire, 10-15' off the ground arranged as an inverted L.

Tomorrow/Thursday evening I plan to be on 3560 at 9PM CDT. 73, Niel

Well I know you do do well Neil. For a moment today I even thought I heard you faintly on or about 7063kcs.
Maybe I will hook up the low power 80m rig (3560kcs) and hammer it everytime I am sitting nearby. Mind you tis not the best time of year anyway however occasionally I do hear some good stuff.we at the very least I would like to get better at it. I have the best luck with my No 19 on AM. Do well on Cw during AWA events or if Lou is testing or playing. If Paul (BUG)is on I look forward to getting an answer as he seems to have exceptional skill at digging out signals. I have made a few QRP low power rigs both SS and tube but the ones around a watt or so are still QSOless so far. I have two antennas and both seem to work well with everything else. What the secret is I would like to figure out.
Been thinking of building Weskit BN-1 clone or finding an old one. So it is not tht I don't have desire to operate that kind of stuff. I have just had no luck at it so eventually began to wonder out loud is it real?
donVE3LYX.
BTW I often check you out on RBN just to see how things are. You are one of my saved searches.

I did work someone on 20m *sideband* a 10dBm exciter stage in an FT-840 that I modified for a transverter use. It was probably on 15 meters. I was in Nebraska and worked one of the big W7 contesters.
Another interesting datapoint, I was operating a fairly large contest station a few years ago and someone complained of a spur about 700Hz below the fundamental CW signal. With the help of a spectrum analyzer we found that indeed there was a spur about -64dB down. At 1500W of fundamental power was enough to cause complaints on a crowded band. That ~1mW signal was enough to cause problems when radiated into a 1/4 vertical. (We changed radios.) Interestingly, the QST review actually showed this spur in the PN spectrum.

Well if I can copy a 250 microwatt beacon (.00025 watt) I can certainly QSO a station running the same power and antenna. Just plug in a key and put an operator behind it. The lowest power I have ever tried to use on the air was 250 milliwatts (.25 watt), which is very high power for this discussion as I think I understood it (the discussion). On 40 meters it was very easy to CQ and get QSOs with that.

I'm not usually a guy who enjoys low power operating but f I had more time and if the fun hadn't completely gone out of building I would brew up some simple flea power thing with a milliwatt or two and get a QSO with it.

Just finished ragchewing with K8JD near Detriot (181 mi.) on 3544.5.
Running a 203A Hartley with 320V on the plate but VERY loosely coupled
to put out only 0.85W to the antenna, dipole up 55ft. He reported me as
599 and holding S9 during the QSO.

Lou,
A while ago I tuned my single-27 Hartley to 20m with a smaller tank coil to "see what its like". I can get about 1/2W out with about 5W input--not real efficient--and the result is a solid 595 at best in the receiver (I'm about T7-8 on 80m for reference). It's probably RF getting back into the supply as it's quite likely the choke isn't optimal. My layout isn't great either, and that is part of the problem too, I'm sure. I didn't spend a lot of time mucking around on 20, since I wasn't what I was designing for. Once I found the right tank coil it had no trouble oscillating, and the chirp and drift are about twice as bad as on 20m...I have no doubt the signal quality could be quite good on 20m if one spends the time to exorcise the gremlins.
BTW, if you are using a superhet receiver with a 9 or 10MHz IF to tune up, make sure you aren't tuning up on your receiver's IF frequency--if you tune your receiver the signal should change frequency. If it doesn't you are transmitting on the receiver's IF.
I remember reading the QST report of the "noontime" 20m QSO between NE and California back in 1924. Apparently, one of them had to key down the transmitter for about 2 minutes to get the TX to stabilize. The first guys to do this in didn't have the challenge of having to zero beat a transmitter and receiver. If I were to attempt this I would plan a good vernier tuning arrangement to minimize hand capacitance for "modern" zero-beat operation. I assume they must have had to do this in the receivers of the era.
Andy K0SM/2

I think , and it is just an idea, but I think that it should be doubled from 7 mcs using a loop out loop in to a 14hhz tank. If I get time today I may try it.
I have seen TNT circuit with a shorting clip for 80m and 40m on the tank however I think better design is doubling to 14mhz. using an old world dummy load will tell you as they don't lie like superhets (or image machines as I think of them) do. A small Hf well calibrated crystal set does not go amiss in an old time shack for testing either. I use one often. Anyway that is the plan.
BTw Mike F, I bought 4 European tubes , Philips equivalents of German tubes. They test very well in circuits , two have the standard 4 pin universal base but two (also the same tube number) have a flat small base with little tags hanging out like soldering tabes except they have a V cast in the base bottom like they belong in some exotic socket. What can you tell me about that style base please.
donVe3LYx
BTW to all my low power buds I am testing now for an hour on 3560 1 watt (band is wide open)and swinging the knobs listening for replies.

Don –

This is the first time I saw your email, so, the other one did not make it. These bases were fairly common in mostly Germany during the ‘30s and the 40’s. I have numerous tubes with these bases and probably a radio or two that use them. I may even have sockets, but, not sure. 73 – Mike

Gentlemen, I'm sure that I'm stating the obvious but no matter how you get to 20 with a SEO, what ever aberrationsare on the oscillator (chirp, clicks, buzz in the AC) will be magnified by doubling or straight operation. I'dguess that neutralizing (if used) might be a trifle finicky. Good luck.

Hello Mike, Joe, Lou, Paul and Don!

Thanks for the warm welcome here in this group!

BTW: Paul is a bit reponsible that my interest in Amateur Radio drifted in the vintage corner. In the late 80th and in the 90th Paul was the ☐net control☐ in the VHF net on 14345. I had to contact him to arrange skeds on 2m EME (moonbouncing). I lost interest in that mode when K1JT presented his software, and everybody switched to digital EME. So I found a new playground on 160m where signals are also weak, and I had fun to work WAS and WAZ from my small home QTH. Here on 160m, I also met a lot of ex EME☐ers from the old time. They were still keen on week CW signals detected by ear. In the 160m chat I also met Paul again, and he reported about his vintage transmitter. I fell in love with this idea, did more research and built my own (Type 27 tube). During a QSO using the Hartley a Czech station reported to use the ☐Paraset☐. Again I had to make researches, again I had to build one. A lot of other spy sets from WW2 area followed.

So that☐s the story! I hope we make it over the pond next winter season using old equipment.

73s from Upper Palantine (Oberpfalz) in Bavaria.

Hello Mike, Joe, Lou, Paul and Don! Thanks for the warm welcome here in this group!BTW: Paul is a bit reponsible that my interest in Amateur Radio drifted in the vintage corner. In the late 80th and in the 90th Paul was the „net control“ in the VHF net on 14345. I had to contact him to arrange skeds on 2m EME (moonbouncing). I lost interest in that mode when K1JT presented his software, and everery body switched to digital EME. So I found a new playground on 160m where signals are also weak, and I had fun to work WAS and WAZ from my small home QTH. Here on 160m, I also met a lot of ex EME’ers from the old time. They were still keen on week CW signals detected by ear. In the 160m chat I also met Paul again, and he reported about his vintage transmitter. I fell in love with this idea, did more research and built my own (Type 27 tube). During a QSO using the Hartley a Czech station reported to

use the „Paraset“. Again I had to make researches, again I had to build one. A lot of other spy sets from WW2 area followed. So that’s the story! I hope we make it over the pond next winter season using old equipment. 73s from Upper Palantine (Oberpfalz) in Bavaria. Tom, DJ5RE

American Science-A Reply.

The Editor, EXPERAMENTAL WIRELESS & THE WIRELESS ENGINEER

October, 1925 Page 856

On page 521 of your issue of May last appears a letter by Mr. D. V. Onslow, under the heading " Power Factor Measurements." Mr. Onslow states amongst other things that " the British spend £50 on research apparatus and LI 000 on thinking, and get results, while Americans spend £1 000 on apparatus and £50 on thinking, and get lost." From the tone of Mr. Onslow's letter I am inclined to think that he knows very little about American research ; has he heard of the U.S. Bureau of Standards ? And does he know that the results obtained in this national laboratory are embodied in publications which are sold to anyone by the U.S. Stationery Office at the bare cost of printing ? Speaking about methods of making measurements, has Mr. Onslow ever heard of the American society for testing materials, or seen the results of their researches, which are published annually ? Again, does Mr. Onslow know that the results of all U.S. Government research departments, including those in agriculture, engineering, meteorology, and many other branches of science, are available to the public ; and that the various scientific societies always have their material available for use by the engineers of the world ? It is to be hoped for the sake of the Electrical Research Association, of which presumably Mr. Onslow is a member, that this gentleman obtains more facts before writing his reports than he did before writing the letter now under reply. As an engineer trained in England and America, I am glad to know that leading engineers of England, as evidenced by their own statements, do not hold the same opinion as your correspondent, but give credit ungrudgingly to our American cousins for the very fine work which they produce. Is it too much to ask that Mr. Onslow spends one shilling in gathering facts before he spends a penny stamp in disparaging the work of his brother engineers? C. R. RUSSELL, M.Sc., M.I.R.E., A.M.I.E.E. 162, Heaton Street, Christchurch, New Zealand.

Having kissed my mortality in my accident in Sept 2014 and survived I have determined not to waste a single day. Drag out your bucket list and get to it! I am about 5 years + or - a day or so behind you. Here in Canada it is just a normal day but the USA made it a national holiday (how kind!) and often hold the Indy 500 on that day. The Germans used to have a song about it (Am Dreisig von Mai ist der Werlt Untergang) which is probably not a good omen however I will take what I can get. Anyway Ron Happy Birthday and make sure to enjoy it.
DonVE3LYX
BTW My friend Rex whom I just saw at breakfast is a ham (probably VE3REX or VE3RR but I forget) asked about HF activity and nets I told him about the MSN tonite so if anyone thinks of it he will probably be reading the mail and could jump in. I gave him the freqs and Joe's net control call.
Rex lives on Big Island. His whole family are hams. Decent folks.

I also wonder about your lines, Ron.

You have to renew a license? By paying for having the call, or by passing another test to proove you still have the knowledge?

In Germany, a license is a lifetime affair. You pay some fees for □handling the frequencies□ and in case the officials have to spend time for mearuring in case of TVI/BCI complaints. If you keep the call, you have to pay the fees. You can give back your call if getting unactive. If you want to become active again, you just have to order a new (!) call and pay the frequency fees again from now on .but no new test to pass the license necessary! Once succeded, no test anymore.

Don -

Here are a few photos of a typical German battery. These were common from around the turn of the century to at least WWII. I also found one on eBay:

http://www.ebay.com/itm/111546565374

The one on eBay seems to be even later as it uses wires for both plus and minus and not a binding post for the plus. These batteries are about 4.3" tall, not counting the binding post, and about 2.2" square. There is also a smaller version, about one third the volume, but I decided not to take photos of them. I can if you like. Something to put on your list for when you visit Germany. I would really like to find one from around 1905 for one of my coherer sets. 73 - Mike

Joe,

Have a look at "Pre-Selection and Image Rejection in Short Wave Superhets," by James J. Lamb and F. E. Handy, QST December 1933, pages 9 to 13 and 76. It describes a pre-selector that looks exactly like the PSK and it is bolted to the side of an FBX. If you are an ARRL member you can find the article through their "periodical archives and search" page. I have the set of QST CDs for the 1930s, and I can always print out a copy and send it to you if necessary.

Hello,

those batteries showed up in various forms. Some of them are dry versions, some with liquid inside. There were dry batteries where you could choose the voltage by stitching through the cardbord on the right point.

You can often buy cardboard boxes (replicas), and install common 9V block batteries as replacement. This is the common way. Some also install inverters for HV, but I was never happy with them (noisy in the RX)

I built a 31/1 ☐Sweetheart☐ receiver replica. This tiny RX was constructed by the Norwegian in Brittish exile Willi Simonsen. He was only allowed to use ☐non confidential parts☐. This receiver was made ☐flacon style☐ and could be hided in ones pocket. They used crystal earphones from brush, normally used in hearing aid units. Power consumption of this little RX was very low. There are 3x 1T4 tubes inside (Regenerative Design, no preamp, 2 audio stages). The heaters are connected in a row, so a 4,5V flat torch battery was used for the heaters. The anode voltage was a 30V dry battery for hearing aid units. After he designed this receivers they were industrial made by Hale in England in large numbers and parachuted into occupied countries.

Those very special hearing aid anode batteries were very small, but they were good for 150-200 hours of receiving (0,5 mA power consumption). The problem was: I found no replacement for this battery. I made the battery box a little bit larger to fit 4x 9V blocks.

Hi Tom -

I was not familiar with the "Sweetheart" receiver, so, I had to look it up. A cute little set. Seems like it would be fairly easy to replicate. It kind of reminds me of the CMS clandestine radio, of which I have several. It is also a 3 tube regen, however it comes with a separate 2 tube transmitter all fitted in a small suitcase.

Wonder if you have ever seen those style of batteries from the 1905 period. I would love to find one for one of my coherer sets which is also from about 1905. This one is made by Bing. Thanks & 73 - Mike

Hello Mike!

Yes, it is pretty easy to make this replica of the 31/1. All parts are available for a very nice prize. The most tricky part is making the box. I used a block of hardwood grinded in form for both parts of the box, and soft aluminium only 1mm thick. It is a must to make those bent edges of the lid, otherwise the hood is not self-supporting. But it works, and it is fun making this correctly. The performance f this receiver is really great. Only a few meters of cable are sufficient, it is very sensitive. I made bandspread for the 40m band. It is also amazing stable, comared to other receivers without frontend like the paraset. I can supply pictures of various stages of the building process if you are interested. I also got very good pictures taken from an original by a French friend.

I wonder which kind of CMS set you have. I know the □briefcase set□ using batteries, but this has a superhet RX. A regens version is very interesting, as this can be made more easier as replica. The IF filters in superhets make things always more difficult. So I am really interested to get more details.

If you want pictures of the Sweetheart I can send some as PM.

Tom -

I have had 4 CMS sets and all of them had the same 3 tube regenerative receiver. It is in a briefcase, not a suitcase, HI. The receiver can work on batteries, but, the transmitter using two 6L6s requires a hand crank generator or some other external power supply. One of these days I hope to get at least one of them on the air. You can get a fair amount of information if you Google "CMS clandestine". I am attaching two manuals to give you an idea. I have never seen a power supply. 73 - Mike

Hello Mike!

I understand! We were talking about different sets! I looked on this site:

http://militaryradio.com/spyradio/mystery.html

Set 1 on this site is listed in ☐Wireless for the warrior, Vol. 4
clandestine radios☐ from Louis Meulstee as the ☐Briefcase set☐. This would
be a very interesting set to build a replica from, but I lack in good
pictures, and the receiver is a superhet.

I think you talk about set 2 on this site. This is also a very interesting one! The RX is indeed regenerative. The interstage transformers are a bit hard to find, but the set should no be too complicated to make.

If you could send high quality pictures, also from inside, that would be very great! I am always collecting infos for a possible future replica project. I only make WW2 sets, so this one would fit.

So I wonder if you still own one and could do me that favour.

I transfered already Sweetheart Infos to Chuck, so if you like them too just tell me.

From: JAMES HANLON
Topic: 13577 Message: 13586

Joe,

I'm glad that you have the means to find that PSK article. Yes, I have both an FB7A and an FBX (non-A model). I have coils for 160, 80, 40, and 20 that I normally assign to the FB7A and for 40 with the FBX. I'm using a 697 "doghouse" power supply with them right now. I added a 2.5 volt filament transformer to the 697 and put a few extra turns on the secondary to arrive at 2.5 volts on the filaments at the receiver. I've got another power supply up in the attic that I think has 2.5 vac output, but it only arrived recently and I haven't gotten it on line as yet. I have one spot in my classic gear lineup for either the FB7A or the FBX, so I sort of alternate between the two. Right now the FBX is in that position and the FB7A is up in the attic.

I found the FB7A in a Kansas City radio store, Associated Radio, on a business trip in the '90s. I brought it home to Albuquerque via a stop in Flint, Michigan. It rode under my seat on the airplane. The FBX was a gift from a friend here in NM. It was rather rusty, but my pal thought I might want to remove the crystal filter and install it in my FB7A. Not me - I cleaned up the FBX and got it operating as well, HI. So now I have a pair. They are still running with almost all of their original resistors and capacitors too. The crystal filter in the FBX is very sharp. It's a bit of a challenge to tune a signal into the peak and leave it there. I run a Heath QF-1 with the FB7A, and it's a lot easier to peak a signal with that gadget because I can tune the QF-1 peak onto a signal after I get it tuned in initially on the receiver. I don't have a PSK preselector, but I do have an RME DB-20 that I can switch in ahead of them. I seldom use it on 80, sometimes on 40 if there is an image problem.

The old FB7A and FBX are quite decent receivers, amazingly so considering they were modestly priced and made in 1933 - 34. National did a good job on them!

Thanks for the info. I make my 90 volt batteries in a wooden Celestial Tea box. I have been putting the terminals on the side but they could and probably should go on the top of the box or end. The size is about right and I think I can make a tag from looking at the samples Mike showed me that will cover it.
Clandestine radios are most interesting. I think the most fun build I ever did and the XYL still talks about it was my POW rig built in the bird box. I put it up on Youtube documenting its very first actual power up. (POW Radio, The Build) . Much it my surprise it actually worked first time. It was built form suff from the garbagge dump IE nothing bought. And runs on discarded batteries to keep it honest. It will also transmit small distances with a rise in voltage. I then built the file box radios which I was using the other night when Andy heard me before I worked Eric. And I have my Telefunken locator radio I show photos of a few weeks back. I saw on War Junk the radio they had in the actual great escape. They took it to the survivor who actually originally built it. Very touching moment. And then there are the commercially produced one like Tom and Mike have. My friend VE3DCX also has a Paraset.
BTW currently I working on a clone of sorts of the old WESKIT Transceiver and am finding it a fun build even if it is outside the normal years for old rigs. I remember reading the ads for years and wondering how one could get a transceiver for so little. And yet when I see the circuit, no reason for it not to work.
Am also playing in 160M for first time in my life. Currently tuned up on 1820kcs. using an ARC5.

(for those that wish they had a National PSK preselector)

As I was looking for PSK information I stumbled across a no modification way to use an SW3 as a preselector. See the March 1983 issue of the AWA Old Timer's bulletin.

Temporarily link couple the SW3 detector coil to the FB7 antenna terminals and run the SW3 slightly below regeneration. Attached is a diagram and instructions from the article.

Hello Lou!

Just some comments about commercial made spy radios. Only few were 100% industrial made. Mostly, the ordered the metal parts, and assembled them in small workshops of the services themselves. So the risk that a unit gets in wrong hands for documentation was smaller. The commercial made versions are often hard to replicate, as they use dicast parts or parts made on a press. The □workshop radios□ are often more easy to reproduce. The early English sets and the early German sets are great to build replicas from.

In Germany, lots of Radio Amateurs were recruted to construct and build the agent□s radios. They used parts and schematics they were familiar with from Amateur Radio times. It is very exciting that the □Abwehr□ (German WW2 military secret service) used parts available in the prewar DASD ware-list. The DASD was the amateur radio organisation in Germany from the beginning until the end of WW2. They offered this parts-service for the members. So early amateur radio sets and simple spy sets are often matching and can□t get devided in 2 separate topics.

Recently some infos show up about Partisan Radios in Yugoslawia. They made the simple radios in huts covered in the woods. Janez, S57J, has made researches and put very interesting infos in the net:

http://www.s57j.com/janez/index.php?option=com_content
<http://www.s57j.com/janez/index.php?option=com_content&view=category&id=12&
Itemid=32&lang=en> &view=category&id=12&Itemid=32&lang=en

Great stuff to read!

Been a ham since my 30s but never had a 160M contact. I have two rigs that are good on 160M. One is an old ARC5 rig I moved to 160M (I have two the other I moved to 80m but they are similar rigs). I noticed Eric was operating on 160M right where I had the old aircraft radio set up at the moment so I dropped him a quick note. He gave me the go ahead and we fixed that little flaw in my Ham history tonite or this morning. I wasn't sleeping but still am not too awake this time of day but managed to drag myself to consciousness and get the deed done. Thank You Eric for taking the time from your contesting to do that. May your efforts be rewarded with success.

Hello Jim.
? ? ? ? ? ? ? I for got to mention something. I think it's great that you have two FB-7 variants and restored the one that was supposed to be used for a parts set to pull the xtal filter out of. I have a similar situation here. I had a FB-7 and a FB-XA at one time and gave the FB-7 to a friend since he wanted it. I kept the FB-XA with a largely incomplete set of coils with it. I could only use it on 80M with the coils I had.?

I later acquired a "AGS" with a full compliment of coils. As you probably know, the AGS and FB-7 use the same coils and can interchange.

I very recently acquired another FB-XA and PSK with almost a full set of coils, and a few "orphan" numbered coils to it. I can now possibly help out my friend who I gave my original FB-7 to with a coil set or two from the spares I now have.?

The FB-XA/PSK combo I recently acquired has a excellent reproduction of the original coil holder for the FB-7 series coils.?

Many thanks again for your information and wish you the best of luck with both of your FB-7 variants.

Thanks guys.

For Don any anyone else who may be interested, here's the rest of the TNT/20M story.

Except for the fact I added a plate current meter (because I just can't resist those old Jewell meters!) and antenna coil (for feeding coax fed antennas), the circuit is pretty much straight out of December 1929 QST. I kept the original series B+ feed. I understand and accept the high voltage risks. There may be some minor layout changes. There are high resolution photos from too many angles on my web site which will show the layout. I suppose I was overly enthusiastic about the newly completed rig and went a bit photo happy.

The 20 meter grid coil is 9 turns, close spaced, 1 inch diameter. It is very critical. One turn more or one less did not work. What do I mean "did not work"? I mean the note became absolutely horrible or it went to spread spectrum! The plate coil is 3 turns 1/4 inch copper tubing spaced to be about 3-1/2 inches long with a right angle at one end to take up the remaining inch between the beehives. See photo. That is my "better" UX-210 in the recording. According to some info I got from Lou on date codes, both my tubes were made in the latter months of 1929. Both behave almost identically on 160, 80, 40 but one sounds quite a bit better on 20 for reasons beyond my understanding. The other is more chirpy and likes to take sudden jumps of 2 to 3 kc!

I don't have a bandspread condenser on mine. Tuning rate on 20 is hard to deal with. As I told Lou, hand capacity is a bear! I discovered the best way (for me) to get on a station's frequency on 20 meters is to tune it close by hand, then pull my hand away and lean my upper body toward or away from the rig a bit to fine tune. I can make it move over at least a 2 kc span easily. It may be unconventional but it works!

I still think it was mostly a matter of luck that it works on 20 meters. I tried making grid and plate coils for higher bands but did not have success above 20 meters. I have long had in mind to try space wound grid coils. Given my experience on 20 meters, it may be that one cannot fine tune the grid coil enough with close wound coils. Smaller diameter might be worth a try too. Just ideas at this point.

I didn't try working DX with it on 20. Aside from testing, I was only on once for the Linc Cundall event back when they allowed 20 meters in that. I worked a half dozen stations I think. I have worked England with the TNT on 160 meters and Portugal on 40 meters. Actually the VE7 guys are almost as far away from me. If I had the space to set it up or leave it set up without so much fuss I would no doubt have worked more DX with it. Most of the time the rig sits in the living room under an acrylic dust cover, causing guests to give it odd looks and eventually ask "What the heck is that thing?" :-)

Very interesting story. What a way to go!
Does anyone know what the Memhis Belle had for Radio gear? I had heard ARC5 however that may not be correct.
I am always intriqued by Aircraft HF radios. Especially when they still work.(I may have inherited that interest)
I believe I have the movie "The Memphis Belle" here in a drawer on VHS. How close it comes to the facts, I don't know.

In re: to B17 radio gear: We had a B17G visit a local airport (Oxford, CT) a couple of years ago and my recallas to the outfit that was aboard "The 505", It had a BC-348 and 5 ARC-5 transmitters and a J-38 key. It was avery cramped shack. Definitely not for fat, old guys like myself. :) :) The sparks doubled as top gunner. BTW:non of it was operational. Roger/K1TG

They are pretty easy to get used to, especially since you have already used a keyer. I always used one in the AWA contests and field day events. 73- Mike

Thanks Roger,
That is too bad. The ARC5s are a very ingenious transmitter. I really enjoy running mine. Very simple but decent units. i find them a bit amazing. In fact I have the 160m one the 80M one and have been tempted to buy one for 40M. Mods to use take about a half day. (Split filament supply, disable relay install key jack . Supply screens (I prefer the dropping resistor but have done it both ways. Change the white capacitor on the front of the tank as it WILL fail! Install power cable and plug for shack PSU and away we go!)
I can see the BC 348 as the little ARC5 rxs seem a bit deaf to me. I have a BC454. Wouldn't want my life depending on it.
(BTW been working on the sort of WESKIT BN-1 clone. Almost done. Fun build. Like doing a kit but without instructions. Hope it works!)

Hi Folks,
I have a old Weston Model 429 surface-mount meter that I need some help dating (even if only approximately). I've attached a picture. It's about 4-1/2" in diameter including the mounting skirt. This one is marked "KS 6189" above the dial and also has five patent dates above, the last of which is 1913, and it sports a SN of 22656. All of these makes me believe its "old", but I'd like to get more specific if I can. The shell is black-painted metal, not bakelite, which is appropriate since this sticks up about 2" above whatever it's mounted to and likely would take some knocks. I have yet to find a catalog or advertisement with this model number in it, but I might not even be looking in the right decade or industry.
These may all be clues to someone who knows meters, but I don't and I'd like to learn. If anyone knows some good meter references for the common manufacturers pre-1930 please let me know. I'll keep digging in the meantime.
Thanks!
Andy K0SM/2

Andy –

The KS numbering system was widely used by WE for items that they used manufactured by some other outfit. I would think it was used on an early WWI WE transmitter. Right now it skips my gray matter what the K stands for, but, I know the S stands for Shops. I know the K is the name of a city. It was the location where WE purchased from outside manufacturers and assigned a KS number to all this items. 73 – Mike

The Model 429 is not in Weston's early 1900s catalog, nor in ones from 1939 and later, so 1920s is probably a good guess. I don't have any catalogs from that period, unfortunately.

K stands for Kearney (NJ)......
S stands for System. The numbering system used by Western Electric.

S is often (mis-) quoted as meaning Standard.

This one is marked "KS 6189" above the dial and also has five patent dates above, the last of which is 1913, and it sports a SN of 22656. All of these makes me believe its "old", but I'd like to get more specific if I can. The shell is black-painted metal, not bakelite, which is appropriate since this sticks up about 2" above whatever it's mounted to and likely would take some knocks. I have yet to find a catalog or advertisement with this model number in it, but I might not even be looking in the right decade or industry.

13615. Weskit transceiver

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-05-31 03:46:40 UTC
From: dulmagedon@...
Topic: 13615 Message: 13615

For years I saw the ad in all the popular magazines for the Weskit Transceiver , $14.95 I think it was. Always wondered what it would be like but never had the guts to buy one. A few days ago I was reading a discussion on them and someone was going on at length about what crap they were and how they were designed etc etc. I couldn't find a schematic but N9TY gave me a link. Once I saw the schematic I realized the person doing the talking didnt really know anything about the set and his description of how it worked was a far cry from the actual design. Typical so I wasn't surprised. I decided to build one sort off. I wasn't going to have crystal control but the same basic idea. So I raided my junk box and started the build last friday. The set uses a single tube 1/2 for Regen for an RX , 1/2 for TX. Pretty simple. Original tube was a 3A5 which I don't have but I do have some 12ax7 tubes so that is was that I used. I built it without the schematic but it is hartley based (Now) I finished it this morning and smoke tested it. Tonight I started setting itup and testing. Silly thing works pretty good all considered. I am currently sorting through grd leaks and coupling links. i also have to sync the two coils (One for Tx and one for RX)
I tuned it with a dual gang cap with bandspread as well onthe RX side so have to adjust the Tx tank as close as possible but looks like it will work. So far it is very encouraging. The 3a5 would work as well or a 6sl7 type or even a old 19 for a vintage version but bottom line is it is a usable idea for budget portable rig. .One side of the dual triode does tx only and one side does Rx only. A key with a shorting handle would be an asset and I don't have one (yet) and I need to install a binding post for the antenna . While the 12ax7 is outside the normal years for our stuff the concept lends itself to other dual triodes and might be worth exploring. We shall see when I get all the rubbing done. Fun build though.

Don,

As shipped the Weskit BN-1 was toy.

You made a major improvement when you added bandspread. The 80/40 meter BN-1 receiver tuned from 3.4MHz to 7.5MHz in three turns of the dial including all of the spectrum in between. The "plastoid" cabinet doesn't help the toy impression either. Then crafty ad wording leading the novice to expect coast to coast communications with this set really hurts.

You can certainly build a better dual triode transmitter-receiver but then it won't be a BN-1.

All true and it isn't a BN-1 but the influence is certainly there.
Since I had built my VFO/ buffer using a hartley in a stainless Kleenex box and several of you have worked me on 40M and 80m on my DX60B using that I knew that side would be OK. A 12ax7 despite its small size is a prettty decent tube. And since I had built my first ever regen (in the 60s) using one I knew it would work there.
The question was would one section supply enough for a VFO hartley transmitter and would one section have enough to e a usable Regen with no additional audio amp. Surprisingly the answer turns out to be yes. And this may be a bit of a toy as well however it works. And I think I am in out of pocket probably about $15. Also it runs on AC based PSU without hum . I took the 4 and 5 pin and the centre tap filament pin (for 6 volt operation.) I braided the leads from 4 and 5 using the centre tap 's lead as the third centre braid. Took the 4 and 5 leads to 12Volts AC and took the centre braid to ground through a .01 cap. I am thinking that is why. it could also be done with the 3A5. I think I will spring for an expanded metal shell for it. I didn't draw a schematic but it is just two hartleys. one with regen pot and phones and a 1 megohm/ 200 pf GRDLK and the other with a 15K/680pf GRDLK and a KEY with the plate circuit returned to ground through a .001 cap.. Each hartley has its own slug tuned ceramic coil form.
I will take a breather today as I want to try some 160M AM with the ARC5 (Grey Hair Net?)this morning then go back at trying to perfect it a bit more. The placement of the phones in the circuit has quite an influence on volume. More then I would have thought. It is currently in plate circuit B + but also works well in B neg and if I had a 3 pole dual throw switch that is where it would end up. I will probably sometime do a 19 tube version.

Here are a couple of quick pics of the DN-1 (for Don). I was able to sync the t and r circuits with the R circuit more or less with the bandspread in central position so I can look above and below a few KCs easily.
Fun build but I will soon need a bigger shack. ;>) T/R switch switches B plus and ant between T section and R section. Rig is cathode keyed. I think an ancient version (19tube) would be fun. I haven't measured power out yet but I suspect a 12ax7 triode section could hold its own against an 01A for instance.

Don,

Does your DN-1 track over both 40 and 80 or did you limit it to one band?

If I put mine on the air I'll probably add series and parallel caps to
the receiver tuning cap as a reversible modification to get it to cover
only 40 meter CW.

How does the antenna get to the receiver in the original BN-1? Is it strictly inductive coupling? Seems like they are separated a fair distance. What am I missing? Thanks & 73 – Mike

Hello Don,?
? ? ? ? ? ? ? ?You mentioned trying out some 160M AM with your ARC 5. I'm curious, do you have the screen modulator for it or do you use plate modulation with your ARC 5 setups? I know the screen modulators are fairly common and the plate modulators are very scarce and sought after. Most ARC 5's I've heard on plate modulated AM use a homebrewski plate modulator. Let me know how you make out when you try it

Just a FYI: I have a British "Codar" AT5 MkII I'm trying to make operational for both 160M and 75M AM. It'll do around 5W output once I get it going. The Codar AT5 uses a modified Heising setup with a modulation choke, and is VFO controlled for both of it's bands. It dates to the mid 1960's. The were very popular in the UK, especially for the lower classes of licensees at the time, but extinct here in North America where they weren't sold or marketed. Possibly sometime we could have a 160M AM QSO once I get my set operational.

I was wondering if anyone on the AWA reflector either has a Codar AT5 or has any experience operating one. I'd like to hear from you at my email address: n3ibx@....?

Mod-U-Later,

Mike,

The BN-1 manual says:

The coupling to the receiver is had through the interelectrode capacity of the dual triode 3A5 tube and no direct connection is required for the receiver - nor will it improve reception....the transmitter tuned circuit acts like a pre-selector for the receiver and "peaks up" or makes signals a great deal stronger.

I am pretty impressed with the amount of information in the five page manual. Maybe I was a little to harsh to call the BN-1 a "toy". It would certainly benefit from bandspread but Weskit intended it to be put on the air.

Niel –

I considered that, and even looked it up, thinking that the plate to plate is the only way it would work and did not expect to find it. However it was shown as 0.3 pf and I dismissed that possibility as I felt it was too small considering the lower impedance of the plate circuits. Guess I was wrong. Pretty clever on the designers part. Wonder if it was designed that way on purpose or realized by accident. Thanks & 73 – Mike

Oh it is 830 PM! No wonder no one was on this morning! Embarrassing. Larry, I should be able to hear that easy enough! I have had my 80M ARC5 on the 811 linear but want to try this one barefoot.
Joe, I use a cathode modulator I built. I use it on a lot of my rigs which are cathode keyed and while it doesn't approach 100% mod it does work and I have used it successfully for a few years. It even works on my 2111 Hartley. I am up for a test of your UK rig anytime.
Sounds like there are a few Weskits around in basements. I will still pick one up if I get the chance.
I am going to go down to Studio B now and work on the Tx output. If all go well I will be on or about 7040kcs.

13627. Early thermocouple RF ammeters

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-05-31 21:40:57 UTC
From: aflowers@frontiernet.net
Topic: 13627 Message: 13627

Hi Guys,
While on my meter quest, I have a questions about Early RF Ammeters, specifically the Weston models.
It looks like some Weston 425 meters had internal thermocouples while some don't. The one I've seen the most is labelled in "Amperes RF" or "Milliamperes RF" above the dial. I've also seen some Weston 425 meters that say "Thermo-galvanometer" and just have a linear scale from 0-100 labelled "Current squared". Maybe these are just older or for the scientific market. Finally, I've seen external thermocouples on a bakelite block labelled "Weston 425 thermocouple" or something similar with four terminals--two terminals on a shunt and two where presumably a DC mA meter (or the 425 meter without the built-in thermocouple?) was to be wired in.
My guess is that "current squared" is just some standard DC mA meter in a relative linear scale because these are nominally square-law detectors. This would allowed one meter to be used with different thermocouples and be "always right"....but I'm guessing.
So...
1. What were the external thermocouples supposed to be used with? 2. Did Weston sell the external thermocouples separately or did they come as package with a matching meter?3. Is there some rule or marking that indicates whether a given Model 425 has in internal thermocouple or requires an external one?
Thanks for your wisdom, as always!

I have the power level up a bit but I would ike to see some more. The rig works well all considered. Clean signal. The regen with out an audio stage does a decent job. It is at the bottom of the band just in operation and I am thinking that through on possibilities to move that spot into solid op zone but it is certainly useable. there is no hum what so ever even though it is on a Hb AC supply and full AC filaments. I am quite surprised. In fact it can hear everything my Digital rx does but volume is low. I may build a combo PS and audio amp which would bring it up to good level however there is something neat about faint but copyable signals as well. Sure is fun to run.
I could hear the Grey hair Net but not to operational levles. Just a snatch of a full sentence now and then but nothing solid. I had the Dx394 on for that. Must be other 160M Am activity. I will try and find someone I can hear . donVe3LYX

Thanks everyone for the information on the KS-number on the Weston 429 meter. It looks like the Kearny plant was built in around 1924 or 25, so I wonder if the KS really has to do with Kearny or if it just got associated with it early on after some obscure beginning. Has anyone seen a KS number on a pre-1924 equipment?
Thanks again!

I am having a lot of fun with the little rig. I ordered a 12au7 to try in place of the 12ax7 and have tried a 12bh7 already. I also ordered a 12WD7 which is a two dissimilar triode package . Sort of like having one half of 6sl7 and a 6sn7 in one tube. probably it will be backwards to how I wired my set but it would be an interesting approach and i suspect a good one , even for a regen only. Since the tube that makes a good regen detector doesnt make a good amplifier. Not to say they don't work but can be improved on. I figured buy the tubes while I can .
Playing on and around 7040kcs.

13641. de K1TG - My UTAH Jr.

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-06-02 13:42:56 UTC
From: Roger Kuchera
Topic: 13641 Message: 13641
Attachments: 2 described; binary payloads are missing from this source WARC

GM Gentlemen, I have attached several JPEGs of my UTAH Jr. The RF deck is an original but the power supply isof my own creation. I bought the Jr. sans power supply. I added voltage regulation for the screen ofthe 6L6 to improve the keying. I also used 1N4007s for the rectifiers to cut down the heat in the smallcabinet that is the UTAH Jr. As you can surmise, I am not a purist.

I notice a difference in the nameplate but it may denote a later model of the Jr.

I say repo, or minimal restoration of a very bad unit

1- The power transformer is a replacement

2- The front panel control labels do not match how Utah did theirs

3- The Utah label does not match those in their ads nor 2 examples of restorations (W1UJR and W0VLZ). In fact it looks like a poorly done paper restoration possibly pasted to a metal back.

4- Phillip head screws were not generally in use at that time.

5- Meter called for in Schematic is 0-100, this appears to be 0-150.

Carl Nord

I say repo, or minimal restoration of a very bad unit 1- The power transformer is a replacement2- The front panel control labels do not match how Utah did theirs3- The Utah label does not match those in their ads nor 2 examples of restorations (W1UJR and W0VLZ). In fact it looks like a poorly done paper restoration possibly pasted to a metal back.4- Phillip head screws were not generally in use at that time.5- Meter called for in Schematic is 0-100, this appears to be 0-150. Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-06-02 14:13:15 UTC
From: Roger Kuchera
Topic: 13634 Message: 13644

Hi Lou, Those caps look like Hammarlunds or possibly Nationals. My Jr. has two Cardwells, which I think are originals.

Here's one of those external thermo-ammeter heating elements I mentioned. It says its for a Weston 425 meter, but all the 425 RF ammeters I've seen in this current range have an internal element.
Anyone know what meter goes with this or seen and advertisement for one? This one says 2 amps capacity, and have one that says 0.100 amps. I can put an amp of RF through it and read a couple hundred microvolts on the terminals, so they are doing something. It reminds me of thermistor detectors on old microwave power meters.

  Hi Guys,
While on my meter quest, I have a questions about Early RF Ammeters, specifically the Weston models.
It looks like some Weston 425 meters had internal thermocouples while some don't. The one I've seen the most is labelled in "Amperes RF" or "Milliamperes RF" above the dial. I've also seen some Weston 425 meters that say "Thermo-galvanometer" and just have a linear scale from 0-100 labelled "Current squared". Maybe these are just older or for the scientific market. Finally, I've seen external thermocouples on a bakelite block labelled "Weston 425 thermocouple" or something similar with four terminals--two terminals on a shunt and two where presumably a DC mA meter (or the 425 meter without the built-in thermocouple?) was to be wired in.
My guess is that "current squared" is just some standard DC mA meter in a relative linear scale because these are nominally square-law detectors. This would allowed one meter to be used with different thermocouples and be "always right"....but I'm guessing.
So...
1. What were the external thermocouples supposed to be used with? 2. Did Weston sell the external thermocouples separately or did they come as package with a matching meter?3. Is there some rule or marking that indicates whether a given Model 425 has in internal thermocouple or requires an external one?
Thanks for your wisdom, as always!

Topic: 13611 Message: 13647

A little more info on that Weston 429 meter....apparently the 2BH phone transmitter in the August 1922 issue of "Radio" used them:
(p. 17, bottom of first column)
"The meters, with the exception of the
antenna meter, are all of the new type
Weston, models 429 and 431, flush
mounting." (c.f. http://www.americanradiohistory.com/Archive-Radio/20s/Radio-1922-08.pdf)
The whole article describes a monster transmitter with pictures and detailed components.
My meter is not flush mounting, but it is a model 429. It's unclear if the "new" refers to the model or the fact that it is flush-mounting, but Weston was making it in 1922. So there's a datapoint...

  Thanks everyone for the information on the KS-number on the Weston 429 meter. It looks like the Kearny plant was built in around 1924 or 25, so I wonder if the KS really has to do with Kearny or if it just got associated with it early on after some obscure beginning. Has anyone seen a KS number on a pre-1924 equipment?
Thanks again!

Subject: [AWA Group] Weston 429 meter [1 Attachment]   Hi Folks, I have a old Weston Model 429 surface-mount meter that I need some help dating (even if only approximately).

I've attached a picture. It's about 4-1/2" in diameter including the mounting skirt. This one is marked "KS 6189" above the dial and also has five patent dates above, the last of which is 1913, and it sports a SN of 22656. All of these makes me believe its "old", but I'd like to get more specific if I can. The shell is black-painted metal, not bakelite, which is appropriate since this sticks up about 2" above whatever it's mounted to and likely would take some knocks. I have yet to find a catalog or advertisement with this model number in it, but I might not even be looking in the right decade or industry. These may all be clues to someone who knows meters, but I don't and I'd like to learn. If anyone knows some good meter references for the common manufacturers pre-1930 please let me know. I'll keep digging in the meantime. Thanks! Andy K0SM/2

My dissimlar triode came today. The company supplied an ECC832 which is the Euro equivalent of the 12 series tube. I feared it would be pinned out opposite to my circuit and I would have to butcher the set and rewire but I got lucky. The 12ax7 style half is on the regen side and the 12au7 style half is on the Tx side. Key down input to plate is 21ma at 285volts. A bit high for this tube but not much.
This set really needs an audio stage and I have a 12aq5 which may get volunteered for AF duty. I am hoping 40m opens up tonite. It was quiet before supper but I would like to do some operating. Still working around 7040kcs.

Hello Don,
? ? ? ? ? ? ? ? The 12AQ5 you selected should provide you with plenty of audio to drive a pair of "cans" ?or even a speaker with plenty of audio to spare. The 12AQ5 is the equivalent of a 6V6 in miniature tube form with a 12.6V heater.?

The best of luck making plenty of contacts on 40M!

Thanks Joe.
It is a not a tube I have used before but I knew folks used 6aq5 tubes for PA applications so i figured it would do the job and the 12v heater helped me out with my set up. you advice confirms that. It says in the specs screen take same voltage as plate at full throttle. I usually steal screen voltage through a dropping resistor from the plate circuit so this is a new deal to me. I may put a resistor in there anyway to keep it reasonable level, maybe 10k or something and see what happens. Spooks me having it the same. I will see if I have a good tube socket tonite as the XYL is at a hen party. I have room on the chassis for it so it should be not too bad. Now to use a transformer or resistance couple it is the next decision. I have done both in the past and have no particular preference.
In between this I will be pumping some Cq s out on 7040kcs since I am on a roll this week anyway. (Won the Pot for the 50/50 at cruise night last night. That is something that only ever happened once before)
What was that old song? When you're hot you're hot and when you're not you're not! I am usually not!

Hello Don,
? ? ? ? ? ? ? ?The decision whether to use resistance or transformer coupling can be a tough one. Particularly if you don't have the specific interstage and or output transformers in question. Resistance coupliing has its advantages but at the sacrifice of gain and output. I personally think that a 12AQ5 will have more than enough gain to run a small speaker at decent volume even if resistance coupling. Like I previously mentioned, look at it as a 6V6 and I think you'll understand. Besides, if you resistance couple the output you forgo the added expense of an output transformer.?

However, if you happen to have a suitable output transformer handy that is not being used, why not incorporate it into the circuit? I think you need a output transformer on the order of something like 5000 ohms or so to correctly match the 12AQ5.?

I too get a little spooked with desling with circuits that the tube(s) use the same voltage for the screen as they do the plate. Like you mentioned a 10K or so dropping resistor would cure that situation at the expense of less overall gain of the tube.?

Whatever you decide to do I wish you the best of luck and a lot of fun.
\
Best regards,
Joe Cro N3IBX

Thanks Joe. I think I will use the resistance coupling since I should have gain to spare. In fact I found a socket last night. prewired it and mounted it. braided up one of my heater supply cables and wired the filaments in. I just have to move the phones to the 12aq plate circuit, pop a resistor in place of them to fake their load and resistance , tag the grid resistor and cathode resistor with bypass to ground and I think we are away.
There was a CW contest on last night and even without the amp I could copy 100% may of the stations although not strong. The set tracks well with the Tx and rx on a dual gang tuning and identical coils . I set the slugs in the coils so the rough tracking leaves the bandspread cap at its half way point. I can then easily swing up or down , finding the station quickly. I am surprised by this little rig. Still I need to log a few contacts but with power input at 5.9 watts and nothing goofy in the output circuit it should just be a matter of time. Note is decent and for some reason no AC hum on the signal or in the regen.
BTW What year was the 19 tube introduced? If it is 1929 I may build a vintage version.

Apparently Lou's not the only one with such an itch. I distinctly remember some suspicious (and also suspiciously familiar) people tapping a key connected to such a device at the Rochester Hamfest last week. It was clearly of superior technology to Kruse's since there were no reports of molten brass or flaming rubber falling from the sky.

Hello All,
? ? ? ? ? ? ? FWIW, I used to have an old spark gap type of electrical Diathermy machine that was older than Moses himself. One day I had the great idea to turn it into a low power spark gap transmitter by somehow keying the B- of the thing. With a little modification here and there I got the thinhg to work. We're not lalking about a lot of power here since the thing only produced about a .250 inch spark gap. Even in spark venacular that's not a lot of power, but transmit it did.?
?I just about completely took out the AM broadcast band of a test receiver, and static was heard all the way up to about 30MHZ which is where the receiver stopped. Obviously the transmitter was untuned and created havoc wherever it could be heard at.?;

I had my fun with it and then converted it back to what it originally was, and later sold it.?

\Best regards,
Joe Cro N3IBX

What interests me even more is a Fessendon style alternator. Still a very practical device at LF and no gap , no spark and no tubes . Recently i saw a fellow using a stepper motor to make one . For instance a die grinder runs typically at 20000 to 28000 rpm. or around 450 to 466 revs per second. Add a 8 pole 20 pole iron based toothed wheel and a magnet energized pickup and there you are at 9khz . Double that and you are at 18khz. Sinewave , pure clean . In fact i suspect taking a old spark gap set up and removing the spark and replcing it with a magnet pickup (Permanent with a good size winding) would immediately get rid of tthe spark which is the evil source of spurious RF and a pure sine wave would be produced. which is how Fessendon probably came to his design. A late 70s car distributor for electronic ignition works exactly so. parts are still avaiable . The sine wave is used to trigger a control box there to generate a spark but without that it is just an AC signal Spend years running an osc scope in my own shop, in college and for KAL Equip out of Kalmazo and demonstrating often that distributor signal. Anyway that is my dream.
I try not to think about it but has been on my mind since I first read of his exploits since it is technology I am very familiar with.
I will go back in my cave now but the subject is very interesting whether you are a sparky of a hummer.

Joe, perhaps it was getting into the receiver IF? From what I've read, there should be very little energy from a spark gap at 30 MHz.

Here is a photo of the business end of the finished transceiver. The 12AQ5 audio amp is to the left rear. The Rec coil near it with the band spread ahead of it. Above is mounted the regen pot. The switch which switches B+ and the Antenna is on the panel in the centre and the RF plate choke (homebrewed) stands right behind it. I connected the choke south of the switch so it is in duty on the Rec function as well. Didn't know if it would work that way but it does. To the right is the dual gang variable cap which does the main tuning for both Rec and Trans. The Section used for transmit has a padder cap to bring it closer to the value for the Rec cap section with the bandspread. Then the coils were slug tuned till with the bandspread set in the middle both transmit and receive are on the same freq. This allows easily for tracking corrections and freq can be swept side to side when looking for an answering station. Works pretty good. The ECC832 tube is a disimilar triode with one side (rec) like a 12ax7 and one side (transmit) like a 12au7. This allows the best of both worlds as the receiver is quite sensitive but transmitter still has some grunt. Still need to log a QSO. Working mostly around 7040kcs. If that doesn't suit anyone I can move anywhere on 40M.
It was a real interesting build.

Subject: [AWA Group] Need help: tactical radio identification [1 Attachment]

Hello group members!

Sorry for bandwith....i have something a bit off topic. But I know there are experts for green radio among the group members, and I was asked for help to identify a tactical radio that might be US origin.
Anyone knows the radio on the picture my friend sent to me? It might be from USA....so maybe I have luck here. There is no label on it!
Thanks in advance!

Tom, DJ5RE

13698. de K1TG - RE: Part needed response

Gentlemen, Let me first say Thank You all for the response and extra info.

I may be mistaken but I thought a 1625 was a 12.6 volt version of an 807. The actual tubedesignation is unimportant in my application. As long as it has a 7-pin Medium base (per RCAdescription). It will be used as a power connector to a 7-pin, wafer type socket on the rearapron of my Gross CW-25. Micanol would be dandy.

There is now huge hurry to get it here as I am still trying to hunt down proper tank condensersand coil info.

Of course, I will gladly pay the freight or some sort of swap.

Have a great day.

Gentlemen, I stand corrected, the venerable 1625 does have a Medium, 7-pin base and wouldcertainly fill the bill for my application. So a "busted" 1625 works.

GA Mike, Thanks for the tube/tube base. It may be a bit of a nitpick use the same pin configuration. With allthe other stuff that is missing from the CW-25, every little bit helps.

I'm against the wall with coil data and I may have to do some R & D with my GDO to find valuesthat will work. I suppose if this refurbishing facet of ham radio was easy, everyone would be doing it.

Take care and stay well.

I built a PSU for the little rig today inside a small shack speaker cabinet.. Seems to work quite well. Input for TX is up to 6.2 watts. Once warmed up thoroughly it seems to settle in a work well. 3 to 5 minutes is about wht it takes to get fully warmed up. The RX works on the new supply however I may have to add some resistance as the rx is running too close to full throttle. BTW it does have good ears. It seems to be able to go in behind what my other Rxs can hear. I am going to use it as is for now and do some pondering before I mess with it. Still hanging around 7040kcs whenever I am in the shack.
I find myself wanting to leave it as it is. I think it will work pretty well.
donVe3LYX.
BTW Tom. That Green rig has to me the look of the MacKay company. I had one of their non Military oommunications rx s here and it had the same style of digital tuning. Almost indentical.

I've never seen that particular set before, but it sure looks like an interesting radio! It appears to be a transceiver, correct? It looks very simple to operate, but somewhat limited in capabilities. There appear to be no controls to select receive bandwidth or AVC time constant, for example.

I will forward your email to a friend that is into green radios; I'd be surprised if he couldn't identify it.

Larry –

I have close to 100 “green” radios from various years, and have yet to see this one. Mil backpack radios did not have the additional controls you mentioned. They were meant for battlefield operation and with easy man/machine interface. On first quick look I thought it was a PRC-74, but, it is not. That was why I offered the suggestion, which Tom did follow up. Hope he lets us know the outcome. 73 – Mike

Don,

Congratulations on your 12AQ5/ECC832 transceiver. You consistently have better results with a regen than I do.

Please post a schematic with parts values. I and (I'm certain) several others would like to repeat your experience and use it as a basis on which to build our own expertise.

tnx es 73,
Niel - W0VLZ

Um well ....I don't use schematics for regens or simple txs anymore . So I would have to sit down and draw one and circuits are already a dime a dozen. However here is a description that should do the job.
It is a hartley osc. (gridleak at top of coil, centre tap (and it is at the centre) to cathode and bottom to B-neg. Main tuning and bandspread cap are across the coil from top to the bottom of the coil. Antenna comes in from a 4 turn link at the top of the coil (grid leak end) I use single feed so one end (closest to main coil winding)is grounded and the other end (top)to the antenna single feed. Gridleak is 1 megohm with 220 cap in parallel. Plate is supplied by a 250K pot across the B+ and B-. Wiper feeds a resitor 5k which is stnding in for the phones on a two stage regen and that feeds the plate. An Rf choke is in the circuit between phones and plate (normal placement although I have put it other places too with good results.) I am using on this one 1/2 a ECC832 tube bt that is the same as 1/2 a 12ax7 . I feed a 12aq5 from there with a .01 Cap (you could use a .1 but the extra freq response can be a pain for hum so i dont.) Now it isnt necessary to use a 12aq5 really. The other half of a 12ax7 will also do the job. Bias it about half way in lieu of a volume control. (The .01 cap of course goes to the audio tube grid but you know that.) I adjust the voltage to the audio stage with a resistor in series with its plate supply because if you power the audio too high it picks up house wiring hum and all.) I measured it and I have about 120 volts on it currently. Cathode resistor can be anything under 400ohms with 250 ohms being my favourite bypassed with a electrolytic of say 10uf and 25 volts. Not critical. I put a 10K resistor from the plate supply to the screen (using the other half of a 12ax7 there is no screen so it would be a non issue.) The phones are in series with the plate resistor. Sometimes it helps to bypass the resistor to ground if the regen is stubborn. Value not critical, say ,001 or something but only if needed.
If it passes the smoke test turn the regen till you hear a slight squeal or whistle with antenna connected , Tune it further and you will find some signals or ambient band noise. Tune till you hear what you want. The more you run it the better you will get.
This one surprises me as it seems to reach in behind the noise and I can copy fellows in you area I can't even hear on the Dx394 or the Dx150 com rxs. It takes time to get used to running a regen and they are perschnickety but they are great performers and addictive. (I haven't counted recently but I think i must have now 15 or 20 running currently)
Oh yeah! One thing when you get it working good. DO NOT improve. the circuit or layout! Leave it alone.
Anyway not hard. Build the Hartley build the Audio amp. Make the hartley feed the audio amp and put the phones in series with the B for the audio amp and they will sense changes in load and you will hear it all. A hartley style regen can handle a big antenna. An Armstrong style can not. I discovered over the years a lot of the theories of how regens work are overcomplicated and suspect to be polite. They really are just an underpowered osc with a set of phones sensing changes in load in sync with the incoming signal as they strain to reach oscillation.
So could one under power their hartley transmitter with set of phones in series with the B voltage and hear signals? Yup. Tis really that simple.

An Rf choke is in the circuit between phones and plate. SHOULD READ
An RF choke is in the circuit between 5k resistor(which is standing in for where the phones would be it a one tube regen) and plate.
I originally built it as a one tube regen or single stage and it worked quite well but too many birthdays has hampered my hearing so I added the audio tube. It was certainly usable though as a one stage regen . It was a toss up whether to leave it or add the second stage.

I ran across an interesting book last night: "Practical Amateur Wireless Stations."
It is a compilation of practical construction articles by the Editor of The Wireless Age magazine. It's from 1920, and as you might expect, there is quite a bit of spark-era building guidance including how to fashion a hot wire ammeter, assemble a home-brew spark gap, and build transformers. It's a really interesting look into the creative minds that built amateur gear before the broadcasting boom.
My favorite so far is the electrically-operated keyer utilizing eddy currents in Chapter XXXVIII.
On Google Books (public domain):
https://books.google.com/books?id=EqsoAQAAMAAJ&printsec=frontcover&dq=Practical+Amateur+Wireless+Stations&hl=en&sa=X&ved=0ahUKEwj81rye1Z7NAhUhHlIKHQO3BmcQ6AEIHjAA#v=onepage&q=Practical%20Amateur%20Wireless%20Stations&f=false
Enjoy!

Speaking of radio, I have spent the past few days spending a lot of time running the regen section of my transceiver. I am somewhat surprised how well it works considering it has so few parts. Joe, tonight , since I remember you saying the 12aq5 might run small speaker I clipped a audio transformer and speaker to the phones jack. It does. Not real loud but ok on strong stations and I have cut back the plate voltage on the amp quite a bit during my search for hum elimination. Since I still have lots of volume for phones and have completely gotten rid of the hum I left the resistor in place. I compared it with an Armstrong style regen I built a while back. The Armstrong works but it isn't even in the same ball game. Altho ugh it was built for a different reason nd served that purpose. This one is a hartley. The Tx and RX track together on a dual gang tunig capacitor but I rarely have to make corrections on the 40m section when gong from RX to TX once I set it up initially. If the only RX I had was this one I would be OK. So far a TX contact has eluded me. All the field strength testing I did indicates it should be OK. My good Txs , ones I have talked with some of you on, all show up on RX at a certain spot a few miles away before leaving earth for a bit. This one is also good there so every set that is good there so far has tuned out to be fine on air. So it should do the job. Just to check I fired up the 211 hartley today and was also unable to raise any one and it usually gets an answer. Hopefully I will log QSO with it soon. There is a contest on tonite with lots of traffic so I m steering clear as it doesn't appear to be a fleapower contest.

?Hello Don,
? ? ? ? ? ? ? ? I'm glad to hear the 12AQ5 in the audio circuit of your "tranceiver" is working out for you! I'd imagine you would get a bit more volume out of it if your plate voltage was higher or you attempted to increase the output of it by increasing your screen voltage. Either way would work, but with the possible addition of introducing more hum into the circuit. It sounds to me like you've reached a good equilibrium between audio output and ease of use. If it will drive a average 4 inch or so speaker to a reasonable level, which I believe it can, I'd leave it well enough alone.?

Remember, a 12AQ5 is just the 12 volt filament cousin of the 6AQ5, which in turn is nothing more than a baseless 6V6 in a minature envelope.?

Mod-U-Later,
? ? ? ? ? ? ? ? ? ? ?Joe Cro N3IBX

I'm going out on a limb here, Lou, but to me it looks like some sort of receiver ;-)

Seriously, it could be a detector with single RF stage, or a regen detector plus an audio stage (in this case one of the caps could be throttle cap for regen control). Just semi-educated guesses.

73,

Actually, I think not. The early sockets were panel or chassis mounted hollow machined tall jacks to accommodate the tube pins. After that came the molded integrated sockets. These are real cheap sockets made much later to cut cost. I have had British sets for well over 50 years and had over at least a hundred and still have a bunch. So, from my observation and experience I will still say that this set is no earlier than the '30s. 73 - Mike

BTW, as to vintage, I would guess early '30s. 73 - Mike

Good guess, but the valve pin sockets are very early.

An odd mix that...

Hello All, This is just a longshot. It could very well be some sort of 2 valve receiver or perhaps some sort of tuner.
Instead of valves occupying the 4 pinned sockets perhaps each one was for an inductance of sorts. Maybe the device was some sort of Broadcast frequency wave trap used to keep the broadcast band out of the Amateur bands or visa-versa.

Maybe..... Just a SWAG on my part.

Joe –

If you look at the photos, there is an inductor between the two caps. On the sockets the proper filament leads are connected and go to the LT binding posts , so, they are indeed for tubes. 73 – Mike

So that is your club station? Is it in Amberg? If I remember rightly Amberg is about 15 to 20km from Nurnberg. I am sure I remember seeing the sign for it at the corner down by the lake. Since I live in Ameliasburgh, an Amberg to Ameliasburgh would be a fun QSO. I could ignore the difference of Burg(h) and Berg just for the fun of it. Anyway checked out all my 20m connections and the rig and should be ready to go next time. There also used to be a Amatuer Radio Club next door to my cousin's in Metzingen but I was too shy to knock on the door when I was there even though he thought I should. Somedays I wish I had.

Hello Don!

Yes, you are right. We are close to Nürnberg, about 50km in the East. We are surrounded by two very large US training areas, Hohenfels in the South and Grafenwöhr in the North. Both include very big US military communities. Where I grew up in Amberg, there was a small field landing strip, and there was an old HF beacon. One time I got in touch with K9BWI from Colorado. He built up this beacon in the early 60☐ies! The world is small when you are am HAM, isn☐t it?

The clubstation is in Amberg, on the West end of the town. It is a relict of the Cold War. We are close to the ex Iron Courtain, and during Cold War the DL0AO location was an area to store ammunition for tanks. There are dozens of bunkers in our lot. The clubstation is housed in the old guardhouse .with bullet-proof windows, hi. I added an old picture taken from the air by DL4RCF. You see the gate, some antennas and the house. Watch the ☐bullet catchers☐, the walls in front of the doors.

When you say Amberg on the radio it is mixed up very often with Bamberg or Hamburg. Amberg means ☐am Berg= At the hill☐.

We do it next time ..100%!

I have been spending a lot of time at the controls of my new homebrew transceiver. This happened a couple of days ago. I decided to make a audio clip so took my hipstreet pocket recorder down and warmed up the set. Surprisingly at first I heard no good signals but a slight adjustment of the controls brought a good signal into hearing and recorded it. Then I noticed the antenna was unplugged (I never leave antenna hooked up overnite) So when I say it can hear better then my other sets I am not kidding. I was surprised myself. This regen ciruit is as I said before hartley osc based. Unfortunately I still have not had a contact with the TX side of the rig. Still banging away around 7040kcs. Probably be on this morning between 9 and 11 am.

Hello!

Mike made me lick blood with the CMS set. I am thinking about collecting parts for a replica. I spent some time to identify the parts, as I'll be at HAM radio hamfest next week. A good opportunity to look for parts. I could figure out most of it, but one question remains open.
The receiver is made with 3x 3S4 battery tubes. The 1st is the detector stage, followed by two AF stages. Between the stages there are two identical interstage transformers. The part is listed with the following text:
"Type 0-5 interstage audio transformer".
I have no idea what it means? Any ideas? Type 0-5....what's the ratio? Are there any listings?

Thanks for your ideas!

Tom, DJ5RE

0-5 stands for UTC (United Transformer Compny) Type 0-5 audio interstage transformer, plate-to-grid, 15,000 Ohms to 60,000 Ohms, primary 4 mA max 710 Ohms DC resistance. The case is 7/8-inch diameter by 1-3/16 inch tall.

The audio types have discovered these and they can go for up to $30 on eBay.

13757. Current capacity of a "cat's whisker"

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-06-17 13:07:04 UTC
From: aflowers@frontiernet.net
Topic: 13757 Message: 13757

Does anyone offhand know what kind of current handling capacity you can get from a "cat's whisker" using standard 1920's detector arrangments? I imagine this all depends on the contact surface area and such which will vary greatly each time you try to adjust the detector, but what's ballpark typical--microamps, milliamps? I'm guessing that for any given contact too much current flows, the point-contact junction melts and you loose the rectifying properties, but I have no experience with these.
I'm just wondering if anyone has done this kind of measurement or has a reference to it.
Andy K0SM/2

Andy –

Wonder why you are interested in this information? Early wave meters used crystal detectors, even at high power transmitting stations. I have several. I expect the current density is a function of the cats whisker surface area more than that of the crystal size. A good clu may be to look up the power handling capability of some point contact crystal diodes. For example you can look up a 1N34 and a 1N21. These would be two extremes, the 1N34 being pretty bulky, while the 1N21 intended more for microwaves would be more sensitive. 73 – Mike

Hello Tom,

I started work on a replica of the CMS receiver, but became discouraged because I cannot make the worm-drive tuning mechanism and also could not fit all of the parts I planned on using in the original box size. I did find two O-5 transformers and planned on using the output transformer from a military ARC-5 receiver for the CMS audio output transformer. I may still build the circuit in more traditional form with a standard dial as it is an intriguing project as is the sweetheart receiver. Good luck on you project.

Topic: 13755 Message: 13761

Hello again Mike!

Well, every project has some stones on the way to success. I always try to find several possible replica projects. The first step is getting pictures and descriptions. Having that, I can see where the key parts are. I always have two or three projects in mind. I know what I miss and try to keep my eyes open. Sometimes I have luck to find the right stuff, so I give it a try. The CMS receiver is depending very much on finding the transformers. Not only the values are important: As you said- The parts must fit in the box. I would choose a much smaller variable C e.g. 5-15pF. When adding a parallel Trimmer-C to the switched resonance coils, I could make bandspreading for 3 amateur bands. When having it bandspreaded, it is possible to use the normal worm gear wheels sold for model builders. The original has 2 wheels with a spring between to avoid a ☐dead point☐ when turning backward. I don☐t know the proper expression .but I am sure you know what I mean. This is hard to make. But I think with bandspreading it should work with a normal worm gear. If the transformer remain the problem, we could use the Sweetheart schematic. Here, the stages are coupled by capacitors. No hard to find parts!

So I go to the HAM radio meeting with several possible projects. The offer on the fleamarket will show me the way.

We☐ll see! Finding the parts is part of the fun!

I also wish you good luck. If you need more Sweetheart infos, just tell me.

Thanks Mike.
This was a curiosity to me, but you've anticipated where I'm going....
You mention "early" wave meters--how early? It looks like RF ammeters post WWI to about 1925 were either of the hot-wire type or thermocouple, at least among the amateurs. Both of these require heating a resistance element and are fundamentally thermal in nature. Hams definitely homebrewed their own hot-wire ammeters with silk threads. You can find several how-to's in the post-war radio magazines.
I haven't come across any examples in the literature, but I have to wonder if anyone tried to make an RF ammeter with a current transformer to pick off a little signal, rectify it with a crystal detector, and drive a low value milliammeter. This is not different than what most many power meters / SWR meters do today, although you wouldn't have the benefit of toroids and iron powder. I would love to see an example, or at least a reference to this method prior to 1925. It looks like the technology was available.
A 1N34 germanim point-contact diode is rated at 500ma, I think. That should be plenty to drive an early 20's milliammeter or something if that kind of current achievable with primitive cat's whisker construction. Obviously, adjusting a crystal detector is a problem from day to day as the point contact is sure to change and thus change the calibration of the meter, but if you are just tuning for maximum current you really don't care about calibration. You can always shunt the ammeter or tap the current transformer to scale large RF current if you have it, but I'm probably working with less than 1 ampere of RF at 3.5 MHz.
More to the point, did anyone actually do this in the early 20's?
Andy K0SM/2

Subject: [AWA Group] Current capacity of a "cat's whisker"   Does anyone offhand know what kind of current handling capacity you can get from a "cat's whisker" using standard 1920's detector arrangments? I imagine this all depends on the contact surface area and such which will vary greatly each time you try to adjust the detector, but what's ballpark typical--microamps, milliamps? I'm guessing that for any given contact too much current flows, the point-contact junction melts and you loose the rectifying properties, but I have no experience with these. I'm just wondering if anyone has done this kind of measurement or has a reference to it. Andy K0SM/2

Worm gear solution:

http://www.ebay.de/sch/i.html?_from=R40
<http://www.ebay.de/sch/i.html?_from=R40&_trksid=p2050601.m570.l1313.TR4.TRC
1.A0.H0.Xschneckengetriebe.TRS0&_nkw=schneckengetriebe&_sacat=0>
&_trksid=p2050601.m570.l1313.TR4.TRC1.A0.H0.Xschneckengetriebe.TRS0&_nkw=sch
neckengetriebe&_sacat=0

1:100 would be perfect, but the diameter of the big gear wheel has to be
smaller then the diameter of the scale wheel.

Hello Tom,

I started work on a replica of the CMS receiver, but became discouraged
because I cannot make the worm-drive tuning mechanism and also could not fit
all of the parts I planned on using in the original box size. I did find
two O-5 transformers and planned on using the output transformer from a
military ARC-5 receiver for the CMS audio output transformer. I may still
build the circuit in more traditional form with a standard dial as it is an
intriguing project as is the sweetheart receiver. Good luck on you project.

Hello Mike!

Thank you very much for this valuable information! I was reading the first
letter as □zero□, but it is the letter □O□ for ouncer! I searched in the
internet. The UTC O-5 seems to be a very rare item. I found others from this

series, but not O-5. It might become the key part.

An alternative would be capacitive coupling .it works fine in the 31/1 sweetheart. But I keep my eyes open for the UTC O-5 originals. The problem is I need 2 of them .that makes it not easier!

Thanks very much for your help again, Mike!

Also that type of thing is or at least was available from Boston Gear. I had to repair an automotive boring bar in my machine shop once . The feed was a worm with a brass gear like the photo. All I had to do was find the size and they had lots. I bought it with the brass gear hole semi finished and repaired the machine. Bearing supply companies are often dealers for Boston gear and most towns of any size have a bearing supply company. Most common in Canada is Montreal Bearing but BDS as well. You would be surprised at what is avaiable. It seemed I could order any size I desired. This is also found in old Car radios. The tube type with the pushbuttons for tuning. The manual tuner on the left side uses a slow worm /gear drive in many sets. They are easy to find at flea markets as the trend now is to the old look but a new radio inside. I came upon 5 recently. Saved one worm assembly for myself. You need to be a bit creative to see how to steal them and remount so if you need everything laid out in great detail and are neg in thought no point in bothering to look. However if you are an optimist and enjoy the challenge, go for it! Of course the same is true of you just buy the gears. You still have to mount them.

Hello Don!

Thanks for your ideas! Well, with all those combinations available it should be easy to make the gear you need. There are 3 or 4 different „modules“ available where the wheels fit together. The worm has usually 2mm axis diameter, the brass wheel 3mm. So you need silver steel axis and brass rods with 6mm to adapt to the knobs we use. I have a small lathe, so it’s not a big problem.

I also have a worm gear driven variable C in my junkbox, but I don’t want to destroy that to gain the gear.

Hello Don and Bon Voyage! I sincerely hope you and your XYL have a terrific time in NL land! You have to find the time to take a ride on the steal train you mentioned. I think it would be a definite highlight in your trip.

I'm curious about the telegraph items you mentioned. I hope you find some and other curiosities at the flea market for a good price. Possibly even some North American or German WWII radios as well. I hope you find something worthwhile to drag home!

Very best regards and let us all know when you are back home and settled in again, and especially if you found anything "radio" you drug back home.?

Thank you all. The Steam train is already on the list. The trip is one way but the XYL has distant cousins nearby the far end and they offered to pick us up by car when we arrive at the end of the run. It is 24 KM so should be fun. The engine is I think about a 1910 version. I am going to the Teyler Museum in Haarlem on Wednesday. I was in front of it last year but on a walking tour when we did our boatcruise and they said it contained early teleraph displays.The website also mentioned early radio so here's hoping. Anyway last year we got to walk by it. This year with my own tour I am going in. I know a few hams in NL. I used to belong to the Mil Surplus Radio Group and we used to try and work each other Sunday afternoons. The organizer of these adventures had a P call and I could work both the Ps and some D calls on 80m SSB although not well that time of day and that time of year. (Summer) I will give them a heads up that I am coming in case some live nearby. I have been to NL flea markets before. Always surprising. Once was in Middelburg and Gouda, Leyden and Alkmaar (several times.) The XYLs cousin told me Hoorn has a very good market and he is an interesting fellow so I am looking forward to it. I have seen many No 19 sets on display in NL as well as early hb regens so I will keep my eyes open as well as my wallet. Usually you can just go straight to the post office wrap it and send it home which works out very well as opposed to dragging it through the airports and customs.Enuf work dragging myself these days.
Till then

I'm going to attempt to make a capacitor out of mica sheets and foil generally following some 1920's homebrew articles. And I'm trying to avoid some rookie mistakes. To sandwich the capacitor it is suggested to use approximately 2x3" rectangles of bakelite. I have some broken/salvaged radio panels that can provide the donor material, but what is the best way to cut this stuff into a clean rectangle without chipping?
Likewise, how cutting hard rubber panels?
Thanks in advance for any wisdom or experience,
Andy K0SM/2

GM Andy and Group,

From my experience, cut with table saw using a standard sharp carbaloy blade. There will be no chipping and the surface of the cut will be surprisingly finished looking.

If you want a fine edge finish use #600 wet & dry sandpaper mounted on a flat wood block. In the end, the edge will be glass smooth.

13776. Supply voltage for old relay

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-06-23 16:34:35 UTC
From: aflowers@frontiernet.net
Topic: 13776 Message: 13776

I have an old "SP114-G" relay that measures with a 1500-ohm coil. It matches the description of the No. 114 Western Electric relay, so its likely the same thing. What would be a typical (safe) voltage to energize something like this? I assume it was used in telephone/telegraph/railroad circuits somewhere, but I don't know much about these early relays and I don't want to burn out the coil by doing something stupid. It has some nice screw adjustments for tension and throw distance, so I'm hoping it can be an effective keying relay for a transmitter.
Thanks!

I have an old "SP114-G" relay that measures with a 1500-ohm coil. It matches the description of the No. 114 Western Electric relay, so its likely the same thing. What would be a typical (safe) voltage to energize something like this? I assume it was used in telephone/telegraph/railroad circuits somewhere, but I don't know much about these early relays and I don't want to burn out the coil by doing something stupid. It has some nice screw adjustments for tension and throw distance, so I'm hoping it can be an effective keying relay for a transmitter.
Thanks!
Andy K0SM/2

Thanks for your reply. Celluloid is the key word. Apparently this stuff is still made in rods for pen makers and sheets for guitar decorative inlays and picks. The material for guitar pick guards and scratch guards is layered and probably not translucent. Google shows most supplies come from China. Nearly all sheet material is in ornate color patterns.

I found only two examples of plain, unpatterned celluloid sheet. Are there any guitar makers on this list who can tell me whether this material is translucent and not opaque?

Celluloid it was. No longer made. Try hobby shops for some other plastics used for something else and repurpose. Good luck. 73

Sent from my Verizon, Samsung Galaxy smartphone

Can anyone in this group help me find a source of the translucent plastic material used for the backlit dials of antique radios?

I bought some of this material from Antique Electronic Supply some time ago, but upon arrival, it crumbled in my hands. Must have been some very unstable composition of plastic. The material is usually ivory or tan in color and allows light to come through thus illuminating numbers and index marks printed on it.

The people in the plastics houses around here are strictly order takers who have no clue about the technical characteristics of what they are selling and I don't know exactly what to order either in person or on-line.

Help anyone? Mike, W6MAB

Hi Andy,

If you have access to a "tile" or lapidary saw it should give excellent results on both materials.
If the hard rubber doesn't cut nice try freezing it first.

From: JAMES HANLON
Topic: 13782 Message: 13782

If you have a variable supply, just start at zero volts across the coil and ramp it up until the relay just operates. Something like 20% to 40% more than the "Just operate voltage" should be a safe and effective operating voltage for the relay.

Anyone know when the TPTG circuit came out?
Have done a little scanning thru the QST CD, but so
far haven't found any ref to that circuit. There may be
something under other names than 'TPTG'. Any articles
in QST 1929 or earlier or other sources...not really
interested in anything from the 1930s unless it refs
back to the '20s. Thanks.

Anyone know when the TPTG circuit came out?

Hi Bill,

Also called (and assume originally called), the (Edwin Howard) Armstrong Circuit. Seldom mentioned in QSTs, but it is featured in one of Kruse's, "How our Tube Circuits Work" series of articles,
Jan., 1927*. If there is another major TPTG circuit QST article that I've missed, please direct me.

Andy, K0SM has been scouring early QSTs, perhaps he knows of its first mention. Though considering its source, any date after 1914 would be correct.

73, Lou VE3AWA

Besides the Kruse article mentioned, also check out March 1927, pg. 33, "A Flexible Transmitter", F.J. Marco. and some comments on which tank sets the "wave" in a note to the Editor in April 1927, pg. 75, "Tuned Plate and Grid".

Bill, et.al.

Also look for material on the Aero transmitter. Some of WU2D's stuff is up in the forums (AMfone?), but there is a document on the BAMA site with a "sales" article from 'Citizens Radio Call Book Magazine' about the Aero. Mostly a sales pitch, but includes the complete schematic! It's a classic TPTG RF circuit on the upper deck and modulator on the lower deck. I think WU2D's version was power supply on bottom, RF on top. I've also seen one a guy built that was a clone of the original, ie. a phone rig. Here's the place to download it, dated 1928:

http://bama.edebris.com/manuals/aero/aero

GL on your potential build. I've done several TPTGs, incl. on 630M, single and push pull, etc. and they general work well. Doesn't Lou have a push-pull TPTG? Don't remember the QST edition that one was based on, but seem to recall it was a Ross article from 1920-something and originally called for 852s(?). There was a push-pull TPTG rig in the 1931 ARRL Handbook also (you can find a PDF copy of the '31 handbook on the internet) if I remember right, both high and low power versions, the latter using 210s.

BTW.... as I mentioned on the Maple Syrup Net a couple back, I had a 1920/1930s style Field Day setup this weekend and a bunch of guys over. 80M doublet with homebrew open wire line (approx 550 ohm), the transmitter was a 27-24-24-865 job more or less straight out of July 1931 QST, but with a Hartley instead of crystal oscillator. 27 tuned to 80M, first 24 to 40M, second 24 also 40M, and the 865 on 40M. About 10W. Never did get a chance to try her out on 20M by using the second 24 as a doubler.

I also built the complementary amplifier using a 203A from the August 1931 QST article. I had not even tested the amplifier, only having been finished at 1AM Saturday morning!! It is somewhat different in that the grid circuit is composed of the driving rig's antenna coupling coil/cap, re-wired to be in parallel, not series, of course. It was coined as being a good amp for any existing power oscillator or MOPA, We did a quick job of neutralizing while the gang was here and fired it up..... no modern measurement devices in sight, so we were only going on RF current. 0.9 amps into 50 ohm (pre-tuned the homebrew link coupled, balanced tuner with an analyzer beforehand)... so about 40 watts. I was hoping for 100W.... anyways, after most guys left, a couple of us starting messing around with it more, mainly tightening the output coupling of the MOPA and amp tanks. NICE! 1.45 amps, ie. 105W on 40M.

Anyways, I'll have a full writeup and photos on my website in a few days. We used an HRO5 for a receiver; everyone commented on how good it sounded and well it handled. Of course, this is from a bunch of guys that grew up with this stuff and/or has owned one at one time or another. Everyone had a great time and lots of good discussion and visiting, including 153 QSOs with that pile of junk!

Holy cow Eric...what a great setup. Congrats on your excellent construction. If that had been my project, on the same time sked, it would be full of clip leads, wire nuts, twisted connections, tape, etc on a piece of plywood from under the shed....hi. Isn't there an old '20s or '30s QST pix showing a station with a neat layout and wiring vs one that would look like mine....haywire all the way. The videos were also great even down to the chicken in the back-ground....calling CQFD?? I know you guys had a ball...73 de Bill K4JYS

13800. Antique FD And TPTG circuits

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-06-28 10:35:51 UTC
From: dulmagedon@...
Topic: 13800 Message: 13800

We're back! I am sorry I missed Field Day. I had hoped to find activity in Europe but theirs was the first of the month. The idea of an Antique FD though is a wonderful idea. Good Job Eric! Nice article too.
Some discussion I see while I was "out" on TPTG. Some of you may know I have one here built for use in my first BK adventure. On using it which I did that year I could see immediatley why the TNT became the more popular unit. Or the Hartley which has the frew range and the tuneability of the TPTG. Eventually I added an RF sniffer to the TP side and running it became much easier. Going by plate current alone did not give sufficient info to satisfy me I was where I was supposed to be. I did have it going as recently as a month ago though and it does work fairly well. I believe I have worked paul . Lou and Larry with it and perhaps Bill. I used it in the 2014 BK on 40M. I can have it on air in a few minutes any time If someone is curious.
If I was to explore the concept further I would try a few things , probably to give the TG section more dominance then the TP section (Dominant Q) It might be the wrong way to go but my gut instinct leads in that direction. It is not a circuit I am in love with so I may just leave well enough alone. Later today I plan to restat my Station as everything was unplug , unhooked while I was away. Saw lots of radios but none of our style. Was in everything from a ancient steam train (Hoorn Stoomtram) to diesel sub (Den Helder Marine Museum.) Got to look over the radio room without being rushed. Racal Phillips and PYE were the dominant sets I saw in Communications displays. It appears the Dutch Navy favours Racal for Rx. Got to try an anti aircraft gun converted or maited with a simulation screen. I think I need on for myself. A lot of fun. I actually got some hits which surprised me.

I got some early keys pictures and early tubes and "microfoons" Good to be back.

I hope to get a radio fix later today.

Here is a very early Dutch Morse Key . I found this in the Teylers Museum in Haarlem NL last Monday. Unfortunately no flash is allowed in the museum and all light in this particular room was supplied by the windows. I am sorry is isnt better. I used to have a program that i could fix photos from this camera with but itis no longer a serviced program. It needs a sharpen and a lighten click to fix it .I am sorrry but i wasnt going leave without photo regardless.

I took a lot of photos but was limited in time as I left my XYL and her distant dutch cousin at the other side of this part of town visiting the Corrie Ten Boom Museum so I went straight to this area of the museum picking out what I thought would be the most interesting. I had about an hour. They give you an audio device and you enter the number (this one as you can see is 205) Then the description is put to you. I suspect but don't know for sure that one may be able to access it virtually as well as the museum has a good online presence and offers to help access info. I live on a island in actual fact and we have no broadband of sufficient service here so I am limited to dial up. someone with a better provider and better computer skills might find that is also accessible on line. I would not surprise me it is. They claim everything that has ever been here still is.
Since my other post did not appear. No I brought nothing home. Never had any opportunity to buy anything while I was there.

Hello everybody!

I need help from you North Americans. As I mentioned before, DK4NQ and me are seriously planning to make replicas of the CMS set. I started to organize the parts. One part is making me sorrows. It's the 4-pole socket used for the antenna in the transmitter and for the headphone in the receiver. Anyone has those left over, or an idea where to buy them? Also infos about the right name or the producer is very wellcome.
Please look at the attachement. The PINs should be something around 1/10 inch or so.

TNX for your help!

Tom, DJ5RE

Tom –

I do not remember ever seeing those sockets on anything other than the CMS. I would suggest that you try to mold your own out of quick setting epoxy. 73 – Mike

Thanks for your comment, Mike!

I was in hope it is something common, maybe still available.

Yes, if it not the case, it can get homemade by milling the block from a piece of black delrin and inserting the available connectors.

Thanks Tom

I have no idea what a CMS set is so perhaps we could be let in on the secret. I would like to know. However to make a socket and make it look right I have had to do many times. First find an old wafer tube socket with the right metal contacts. Take it apart removing carefully the individual contacts. Decide what materiel you will use for the new socket. I usually use perf board or fiberglass circuit board with copper removed or the old plastic many 20 radios used. Your choice.Proceedure is the same. Mark and drill the four holes in one board and place another board over it and drill again so they match exactly. Make the first set of holes larges enough that the contacts removed from the old tube socket fit in. place the second board made over top and inset the plug or tube or whatever you are making it for. Once you are sure everything goes in Ok with it all plugged together mark and drill the two mounting screw holes. Insert the srews and put on the nuts and tighten. Now remove the plug or tube etc and shape the boards to their desired shape while they are still fastened together tightly. Remove the screws mount the socket in the radio and install the screws and nuts. You should not be able to tell it from an original. Last one I built was a tube socket for a PT215 tube and I am thinking few, if any have any of those lying around. donVe3LYX

Having just bought one, does anyone have any info on these transmitters. I seem to remember a advert in RSGB mag dating from the 50's that showed a line drawing of the transmitter. Was it a series of units VFO,Exciter possibly a RX?

Does anyone have a schematic?

I shall be rebuilding it for use on the air. Oh it has 2x6l6 push pull for AM modulator and 807 O/P

Many Thanks Brian

A good friend, Bob, W4JDQ, is from around Rochester, NY and mentioned his short visit to the W2ICE shack:

It was about 1956 or 1957 and I was enrolled in an electronics program at Jefferson High School in Rochester, NY. We were learning about electronics and our objective was to pass the First Class Radio Telephone, and Radio Telegraph licenses and become gainfully employed in the field. Some of my class were interested in Amateur Radio and chose to take those FCC exams at the same time we took our Commercial tests.

Dr. Bloom one of our professors knew of a well known amateur radio operator in the area and arranged for 4 or 5 of us to go to this persons farm and home. We arrived at a large home in the country and Mr. Bruce Kelley W2ICE met us at the door and welcomed us in. We were ushered into a large room in the home and were shocked to see a modified broadcast transmitter arranged beside a large console which contained a Collins 75A-4 receiver. I remember a large single tube in the final (5000 T I think) which was very impressive and glowed a cherry red when he transmitted. I believe Mr. Kelley told us he had a 3 phase power supply in the basement which powered his transmitter and other equipment. It was dark and in the evening so we were not able to see the antenna system but we were told that he had a 75 meter rhombic antenna system some 50 or 60 feet off the ground in a field on the farm. We either were told or surmised that he worked for Rochester Gas & Electric (the power company) or maybe a contractor who installed power systems. He mentioned to us that he had a large collection of equipment in the basement but we ran out of time and did not see his personal collection.

He was a very knowledgeable fellow and was very quick to demonstrate and explain what was in his shack. He was transmitting on AM at that time and demonstrated how he could whisper CQ into the mike and get a reply from a fellow ham in Germany. Between the mike and the modulator he had a 23 to 1 compression amplifier, which keep the modulation banging up around 90% at all times. The compression amplifier was the same used in some AM broadcast stations at this time. We were a little curious as to how many watts he was really running because we all had been using the 1 KW we had at school. We knew that the transmitter originally was designed to run about 5000 watts and I believe that he said that it required about 8,000 volts plate voltage to run full power.

While the memories of the meeting are a little vague now there was no doubt that Bruce Kelley was a Ham’s Ham and a genuine good fellow. He is certainly a legend and we felt honored to meet him.

Bob

Don –

I am sure you know that these are not real “vacuum tubes”. They are in the family of Crookes tubes often used in Physics classes. I have several. You just apply about a KV or more and the tube lights up in a color depending on the gas used as the filler. 73 – Mike

The compression amplifier was the same used in some AM broadcast stations at this time. We were a little curious as to how many watts he was really running because we all had been using the 1 KW we had at school. We knew that the transmitter originally was designed to run about 5000 watts and I believe that he said that it required about 8,000 volts plate voltage to run full power.

While the memories of the meeting are a little vague now there was no doubt that Bruce Kelley was a Ham’s Ham and a genuine good fellow. He is certainly a legend and we felt

honored to meet him.

No Mike I didn't know that. I knew they were not radio tubes but figured they were an experimental tube of some type and probably very old. Tis a bad day if I don't learn something.
My high school days were unexpectedly cut short. Had to self educate till I got into my trades and college.
Thanks

This is the last of the best from the Teyler Museum that would relate to us. I have a couple from the 20th Century Museum on Oostereiland in Hoorn NL that I think would be of interest.
I was surprised to see this in the display case. I believe it is older then its design looks.

It was just sitting on display in the cabinent with a reference to inductors. In this museum you are kinda on Ur own. The "ladies" who run it are neat and pleasant but not technical. The cabinets are quite high too. I had to stand on my tip toes to get the photo. Some of the Dutch are very tall. Must be something in the water.

I only asked because to me it looked more like an air cooled vintage nichrome resistor element rather than an inductor. I never saw a free standing inductor like that until about the early ‘20s. I would have expected a museum to have real representative ancient stuff. Of course, for the general public, it probably does not matter that much. 73 – Mike

I have been working on the little transceiver since getting back home. Trying to improve its output. Yesterday i believe I had some good success and did some local tests getting the XYL to help. I need to log a contact or a report before setting it on the shelf till winter. So I am calling this morning at 8 AM my time (EDT) on or about 7040kcs (if busy will go down a couple of KCs) I will also repeat at 9AM . If any ears (reply or report by Email)are available it would be appreciated as it is always better with those who understand vintage and appreciate radio. Thank you.

Don, I had you very solid on your CQ. Quite a bit of QSB and some QRM around by copied 80% during our short QSO. Your rig is working! It has a slight bit of chirp and some drift... I had to follow you a bit as I was using a narrow filter to reject QRM. That was not bad considering I have a high local noise level. My receiving antennas are broken so I was listening on the inverted V. It's installed in a non-optimal spot and picks up noise from a lot of sources.

Thanks Louis

I'm afraid the transmitter has a lot of crystal current. I have just tried a HC49 and it chirped like the dawn chorus!. I have a FT171, but on the wrong frequency 7075Khz for CW in the UK, and that behaves beautifully next to no chirp nice tone. It does not have to be a FT171 just large and same pin spacing.

I will give Brian a email see if he has any with the big crystals.

I have attached a Picture of the Qmax B4/40 its very rare in fact it maybe the only one left.

I have gotten interested in clandestine radios. I found a rig acreditied to Germany called an Adapter Nut which pops into the 6v6 or 6y6 final audio tube socket of a 1930s/40s style home cabinet superhet and contains a complete 4 channel crystal controlled Cw rig. To be honest it doesn't look very German to me however that aside the concept is very interesting and very doable. In fact it is so practical I wonder why it wasn't in all the old ARRL handbooks. There is no schematic I could see but I think that is minor. The circuit has to be much like the BE rigs some of us built in later years except with 4 switchable crystals. If one used an old set with short wave you would have it all. You could cess the audio from the same box wit a set of phones (not using the final) BFO is an issue but might be possible to mistune the Ifs enough to detect the signal. Later years a AC DC set would also work. Anyway it intrigues me. I am peering into my junk box now to see of I have anything that would work. I havent committed to it yet but I am thinking. I have a very early 1930s set from the XYL grandmother that still work Probably about 1931 or 32. so no 6v6 but that doesn't matter. Still can be done with whatever it has. Who knows maybe we will have to have a Clandestine Transmitter Event. The air would be alive with Parasets Adapter Nuts and CMS sets.

Hello Don!

I also recommend this group:

https://groups.yahoo.com/neo/groups/LesAmisduParaset/info

Wellcome in the spy scene! My list of replicas is getting longer every year. Once having licked blood it will attract your attention forever! If you need any infos about the sets I made already, I can send you all I have. Look on www.hoeppe.name <http://www.hoeppe.name> If you like one of the sets tell me.

About the adapters: I am not sure about the principle they were used. The agent needed pretty much technical knowledge! He had to know which final tube is in which radio. Then, he had to make modifications in the radio! The receivers had high resistive chokes or resistors in the DC filters after the rectifier tube. The voltage for the adapter had to be taken across the first electrolytic capacitor. There were free pins on the tube sockets, so you could make connections to that pins. The adapter had a shortcut. When plugged in, the high resistive part of the filter was jumpered.

But it HAD to become modified. Nothing for agent □average□.

My opinion .

Tom –

I wonder if this would help you out. I think you can machine pretty close to the original from this piece. Use two of the double pin jacks to make a 4 pin one. The piece is 3.2 inches long and 1.65 inches wide. From those dimensions, you can scale the rest. 73 – Mike

Hello everybody!

I need help from you North Americans. As I mentioned before, DK4NQ and me are seriously planning to make replicas of the CMS set. I started to organize the parts. One part is making me sorrows. It's the 4-pole socket used for the antenna in the transmitter and for the headphone in the receiver. Anyone has those left over, or an idea where to buy them? Also infos about the right name or the producer is very wellcome.
Please look at the attachement. The PINs should be something around 1/10 inch or so.

TNX for your help!

Tom, DJ5RE

Topic: 13832 Message: 13836

Thank you both for the info. I see on both list folks I know form other adventures including Tom and Mike but others as well. I think at the moment I will just build an adapter nut and see how that goes. In all my power supplies I use the 7AC pint out and an octal plug. Even my No 19 and all my AWA stuff. I think I will start looking for a 6v6 final old shortwave parlour set in antiques stores and flea markets. However thanks for the links. As you know Mike I have a Telefunken briefcase Spy radio locator set so I am half way there. My friend Jim VE3DCX has a Paraset so I will quiz him next time he is here. Anyway after building the last rig and noting its excellent performance I realized that making a simple low parts count radio that really works is well within the realm of possibility. So back to the vintage stuff now.

13837. Dubilier Micadon 601 voltage rating

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-06 12:53:14 UTC
From: aflowers@frontiernet.net
Topic: 13837 Message: 13837

Does anyone know what the old 601 Micadons were rated for, approximately? I have a 2000pf one that I'm considering using as a plate blocking cap is a circuit that will probably see about 350V. These are "receiving condensers", but I have seen them in late 20's TNTs and such.
It's the kind seen here in the Dubilier 1922 circular:
http://ethw.org/images/4/45/Dubilier_-_Dubilier_Micadons,_Type_601.pdf
Their use in transmitting circuits in the depression doesn't necessarily imply that it's a good idea. I would do a HV test at something much higher before I put it in a circuit, but I'd rather not attempt to punch through one if they really are not appropriate for this application.
Thanks,Andy K0SM/2

Morning all,
I have been working on this rig for a while now.....simple rig, but I'm just plain slow. Anyway, I got the rig finished recently and put it in a small wood rack which I stained and put it all back together. To finish off the station, I use a National SW-3 regen. It is great fun using a station pretty much like it would have been in 1933. The osc. is from a 1933 'RADIO' mag. article. The tube is a 2A5 and am probably getting abt 8-10 watts out into the sgl wire fed Windom. Am using it on 40m, which has not been very good for low power work lately, but I am still chirping away....actually, not too much chirp...depending on xtal and sweet spot for tuning. Generally works well when band condx cooperate...RBN tells me it's working even when I don't get replies to CQs.

Very nice rig! Sounds like your getting a very respectable amount of power output too!

If you want to try a QSO, let me know a time and freq. I can fire up the FD rig for it's final QSO... I am going to be tearing it down to re-cycle several parts for a new exciter for next year.

13845. Re: [AWA Group] 2A5 Finally Finished

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-06 20:50:00 UTC
From: Eric NO3M
Topic: 13838 Message: 13845

It won't be a complete tear down, but I want to remove one of the unneeded 24A doubler stages, cut the board down a bit (36 in is pretty wide!), and relocate the 27 Hartley osc. It will be my '29 AWA 40M rig. The new rig will use a 24A ECO, grid on 160M, plate on 80M and maybe different doubler tubes (46s). It will also be a triple decker (osc+doublers, intermediate amp, power amp) to put all the controls within reach of the control operator. Basically just ergonomic and stability improvements for next year's FD setup (and perhaps other on-air events with guest ops).

I also need to steal the small Cardwell variables in the original rig for the new rig, only limited luck finding that style at the hamfests this year or online. They are Cardwell 424Bs, about 75-80pF. I think 410s are the same size/style. I'll use whatever similar value caps I have on hand or can scrounge up to put back in the original rig.

Looks like he subbed a 6AS7 for the '45 in the 1932 George Grammar article. Also he's using a transmitting mica in the tank circuit so he can use a smaller air variable for better bandspread, and I see an RF choke not in the original design, probably to use shunt-feed to keep the B+ off the tank components.

I always wondered how a 6AS7 would work as an oscillator - its amplification factor is only 2!

Yes, the 6AS7 was mainly used in voltage regulator circuits to the best of my recollection. I also have never seen it as an oscillator, however, have heard of some of the audio guys using it in amps. 73 - Mike

One of the projects I've been planning and have collected all the parts
for is an OTL (output transformer-less) audio amp using 5 or 6 6080s in
the power output stage. Just would like to see how well it works. As you
know, the 6080 is pretty-much identical to the 6AS7 and was also
designed as a linear pass device for voltage regulator service.

Memory fades, but I think there was a 6AS7 along with a 6L6 and something else in the electronically regulated screen grid supply I built for a VHF amplifier back in the 1980s. It was a weird project for the time period but I needed to do it using parts in my junk collection and wanted to try something different. One thing it was not: simple!

That's my understanding as well. Aesthetically I prefer the ST shape of the 6AS7 over the cylindrical 6080, but I've got a ton of 6080s and only 1 or 2 6AS7s.

Very low: 280 ohms per triode. That's why they are contenders for an OTL
output stage. It can be done with an (almost) reasonable number of them
in parallel.

Doug, a later issue, maybe the next months, has info on an amp using a pair of 2A5s for use with this osc. The whole affair might make a nice project. Tnx for posting the osc. article.

Strange subject. While you folks were looking at the Ebay listng for the 6as7 I was working on a twintriode Mopa I built a year or so ago. I built it with a 6bl7 but was never happy with it. So I had a bench full of dual triodes (octal) laid out and was trying them to see. One I tried was a 6080. It worked but my on board power supply just couldn't handle the load and yes i even saw a whisp of smoke. I had a European 6sn7 (EC something) equivalent but the set does not like it. Could be a bad tube but I have never liked it for anything since I got it. I didn't have a 6sn7 but i did have a 12sn7 and the on board PSU allows that change easily. I popped it i and tuned it up. This rig has a meter which is a big help in tuning. I also built this rig with a fixed cap and slug tuned coil on the osc side (PA is a simple parallel tuned circuit) so tuning is fine.(not coarse). It sounded pretty good on the monitor shack rx so I hooked up the antenna clipped on a ground lead and called CQ on 7044kcs (in case Bill was there ;>) Conditions today were terrible. In fact prop reports lists both day and night as Poor . I expected no rely but had nothing to lose. I heard faintly some one key up then begin to tune. I send a question mark and my call with a K (invitation to transmit) and there faintly thru the noise I heard Mike WA1JAS returning the call. Both of us could hardly hear(reports were 229 and 239) however the lack of any QRM made it possible and we managed to make it work, said our 73s and signed. I couldn't believe it. 466 miles ATCF in poor conditions on very low power. I mean really how much can a 12sn7 make? So the 6as7 version would probably do much better. Hope someone buys it. And thanks to Mike for replying. Unbelievable.

If you would allow me to ask just one more spy radio question. I went ahead and have about 1/2 the Adapter Nut transmitter built. I am picking out crystals and have several in the 80m band that will work in the circuit and hide well. Is there a specific freq for Paraset and spy radio folks to gather on or does it matter? I haven't joined either group yet. Still deciding. Might be better just to watch from the side. Meanwhile solder is flowing. Hopefully be next weekend it will be on the air.

Don –

What is an “Adapter Nut” ? I only found one reference when Googled, and it appeared like it was recently built. Also, did not look German at all. Was it meant to be used by German spies in the US, to use within US radios? 73 – Mike

I don't know Mike. I just found it on a spy radio search and as if you noticed in my first post about it, it did not appear German to me either (and I was also suspicious about some of the components in the picture.) That said the concept is interesting. For instance I know in the past it was not unusual to steal power for a small transmitter from the audio output tube socket. The idea of using that tube as well in the plugged in tx appealed to me as that is what the adapter nut does. I cannot be responsible for misinformation on the web but I do know that the idea is very practical. If not only for a spy for a young hams first transmitter as well. A very simple deal. Simple is almost always extremely effective as well. So I elected as captain of my own shack to build one. Not exact to the picture but same idea. Whether it is historical correct or not ??????. Using the 7AC tube pinout comes up with a Tx that will work in many radios and also Pa systems. I elected to use an old style light switch box and plate for mine and to cable it rather then direct plugging to avoid spacial problems with the higher tube stuck in the nut. ("Nut" BTW sounds very British to me)
I live about an hour away from the old Camp X site which is recently getting some attention and where many Allied Spies were trained and where some famous intelligence agencies first got their start and directors so it interests me either way. Recently (a month ago)one of my buddies did the walking tour there. The idea of a small set by 1940s standards that could be carried into a home easily and plugged into a normal parlour radio for transmitting , if it wasn't used it should have been. Anyway thanks for the input and thanks Tom for the freq info. Good bad or indifferent it is getting built. Hopefully it will work decently.
donVE3LYX
BTW I have thought a lot recently about clandestine radio. Much is made about the regens being detectable say in the Parasets for instance. I guess because I have built so many regens and experimented with them listening for their hetrodyne on a monitor rx. Limiting the regens regen control range can reduce that to a minimum and cut down its detectable range to a few feet or less while still giving CW copy however that becomes a moot point when you press the transmitter key.

So Mike in answer to your observation which were similar in thought to mine I found this out. that one on the picture is a replica built to represent the originals. The originals were known as adapter sets (Zwischenstueck ("between piece" is how my brain translates it. Tom?) and were not ascribed to any particular manufacturer or carved in stone design so mine will be built in the Fabrik D Karl Dolmetsch which would be my proper family name before the forced respelling on immigration and any design I choose if it s period correct and are he components should be OK. These sets predated the Pocket sets which came just before the SE series (Sender/Emphanger, Transmitter/ Receiver).
Before the war here in The County which is a stratigically situated island of sorts hanging out on the north shore of Lake Ontario there was a young man who came mysteriously from Germany. A Metzgerei or butcher by trade and lived among the people here. He spent a lot of time at my grandfathers home and my dad a teenager knew him well. He sometimes went back to his home in Frankfurt for Christmas and I have several letters he sent to my great grandparents and grandparents from there. He referrred to my grandmotheras "mom" so he must have spent a lot of time there. I have pictures of him with the family. He fell in love with a local maiden and was to be married but was found murdered hanging in his barn on the night before. My dad saw when they cut him down and told me of some of the reason when it had to be murder and not susicde as the police wished. My Grandmother sent my Aunt around to all who knew him and there rasided enough money to give him a decent burial in the local church cemetery and a small stone. His name was Wilhelm Nickolaus and I know where the stone is and have often visited it when there as he was a good friend to my family. My Aunt in retirement visited the family in Germany on a European holiday. She couldn't speak German so used someone to help her but she told me they thought he was a soldier who died because of the war. He died before hostilities were declared so that didnt make sense. My aunt is gone and so is my Dad and his brothers now but I have often wondered. What was he doing here? And now I wonder where is his adapter set? Yes I could be wrong but ?????????? His home still stands and is not far away.
I know why he got along with my family as there is a way of thinking that stays in the blood no mater where the family goes. He would have felt at home with them. Grand Dad would not have been suspicious although my Dad's older brother was.
Anyway this is probably what is fueling my interest. Right or wrong.

Hello Don!

Yes, your translation is o.K. ☐Zwischenstück☐ is a piece you need to connect two things together, in this case the tube and the radio. By doing this, you get a transmitter. Most adapters you see in the internet are replicas. I never saw an original.

This is an interesting story about that man! There were spies all over the world. I red a book about missions where some were brought to north america by submarine. The adapters were low power devices, made for ☐single hop☐ propagation inside Europe. From Canada, you need a more powerful set. The main unit used for that purpose was the SE90/40. As you mentioned right, SE = Sender/Empfänger (Transmitter/Receiver). The number following SE is the development number of the set. The higher this number, the later in the war it was constructed. The number after the dash (☐/☐) is the power of the set. The picture shows my replica of the ☐overseas☐ set SE90/40. The TX is VFO controlled, using a RL12P50 final tube. With the white switch in the middle you can choose 2 frequency ranges. There were sets with higher QRGs for oversea☐s service. The suitcase is very heavy. Often, they had this sets also in the local embassy. I wonder about the construction of this set. In the original schematic, the have full voltage of the final tube (700V) also on the anode of the tiny CC2 oscillator tube. I am sure this tubes did not last very long. And then? You will not find the CC2 in other countries. Send another submarine?

A crazy detail, isn☐t it.

Getting interested in wartime spy radios is always much more interesting if you learn also about the stories behind this sets.

Have fun!

Tom, DJ5RE

What a good job you have done on that!
I learned while searching that the early spies were sent out to watch shipping lanes. I just found that out just this morning. We live on the main shipping lane for the Great Lakes and right down where Wilhelm lived or Willy as my family called him you can see the lakes traffic easily. It would not be hard probably even today to see 3 or 4 ships from there. I could be wrong but I wonder because never understood why he was here. And folks who came later even in the 1950s knew about him even though the locals had long forgotten him. One lady (Frau Fleischman) from your area of Germany who came here in the 1950s and who helped me with my language aquisition (I Vill not speak to you in Englisch from now on!) was here one day and started telling me some of Willy's story in German. When I told her I know about him and how she waved her hand wildly in front of her face, became very frustrated and her and her husband got in the car and left within minutes. I wondered then how she knew the story as she came long after the war. So you can see why I wonder. She had no idea it was my familie he was friends with. We know they caught a U boat in the St Lorenz (Lawrence) during the war and I have a captured Telfunken DF raincoat set (I sent Mike a photo) that the the Canadian Goverment had till the 1970s. If a U boat made it into the Great Lakes it would not be any trouble to communicate I think. And it would not be a big deal pre 1939 anyway to be studying such things as shipping traffic if that was the case.
Anyway, I am boring everyone with my tale. Sorry.
However This winter I hope to work you with my Adapter despite the distance. "I am pressing my thumbs together" ;>)

Dear Don!

I asked a friend from UK about the word ☐Nut☐. He said it☐s not British origin . He had also no idea where it comes from.

So better call it ☐Adapter-Transmitter☐, hi.

The story about that German is really strange. Monitoring the ships near harbours was always one of the tasks of those agents. If you want to read something very authentic, try to find the book ☐Two eggs on my plate☐ from Oluf Reed Olsen. Oluf was radio amateur and wartime Norwegian resistance fighter. It☐s a great book. He wrote it in the 50☐ies. I bought mine in an antiquariat in England. I love that book!

BTW: Do you know the story of the Canadian Gustave Biéler?:

https://www.youtube.com/watch?v=QAXOGQBns_s

Gustave Biéler was excecuted only a few km away from here, in KZ Flossenbürg. His daughter Jacqueline had a lot of correspondance with the memorial center in Flossenbürg. I red the letters in the archive.

73s Tom.

Ok, He would have a hard time convincing me as I have known some Brits here who call anything small with flat sides a nut but not a hill I want to die on.
Mine is done and was on the air 15 minutes ago. Sounds not bad and power is good I think. I had a 6v6 in it. (48 ma at 272volts I believe was what I saw on the meter). I had it on my light duty PSU which is wired with a 7AC octal pinout for testing. I will try it in a receiver perhaps later tonight. Final freq installed came out at 7051.4 with the 7050 crystal. You can see the crystal to the right of the tube, also on the right side of the tube base you will see a Christmas tree bulb. I often use them for cathode resistors and indicators. When adjusting the slug tuned tank circuit I use the bulb to find resonance. It works very well. I should probably bypass it with a cap but it is so low in ohms I felt it would not be necessary. The first pic shows all the spy would need to bring. The box and a crystal. The host receiver supplies the tube. I did not make it like the one in the photo because i tried several set and only have one here with enough height inside to allow for the adapter under the tube. This design doesn't care. The set can use a 50l6 like an old table radio. I have a couple of sets with a 6y6 final I can try it on. I will have to get them near the antenna so I can use it. There are a lot of final tubes of the octal variety that use that pinout so it should be and would have been very easy finding a host unit. I have to come up with some sort of a clandestine style CW key. And maybe it doesn't need to be an actual key. Anyway I will be trying it tonight on 40m to see how it gets out.
I am going to look for that book.
Gustav's story doesn't pop into my head but it has been several years since I read the Camp X book which lists a lot and tells the stories. In fact if I do get to Nurnberg this Dec for the Christmas markets I will bring you a copy of that book. I started a file on Willy N BTW. There seems to be more to this story then I originally thought.
Anyway any one wants to listen tonight I am going to try the rig out probably between 7Pm and 8PM EDT (my time) 7051.4kcs(That would be during Wheel of Fortune and Jeopardy)

Isn't the only way from the ocean to the great lakes up the Hudson and via the Erie Canal? The canal had several locks; how would an enemy U-boat be able to get all the lock operators to cooperate? Doesn't seem very likely to me. I don't even know if it's physically possible for a U-boat to negotiate the locks.

I'm pretty sure the Sunday PM AM Net, and the 40M SSB net that meets at
noon on Sundays are both still going, as well as the Bruce Kelly Net.

Also 160M Monday night (that's tonight!) at 8PM on 1945 KHz. Youss truly
has (somewhat reluctantly) taken over net control duties from N3IBX.

No We have this great river the St Lawrence which is similar to the Rhine in Europe.. Halifax is the first major port, then Quebec City. The river ends at Kingston where it turns into Lake Ontario which I live on and it is the first of the Great Lakes going east to west. People have been sailing up here since the 1600s. And yes they did catch a sub in the St Lawrence during the war. Tis a matter of history and nothing to do with me or opinions. This river is how this country Canada was settled. Surely you are teasing? Anyway here is the inside of the little rig. Not pretty but works decent it seems. donVe3LYX

It may have been difficult from Montreal on but the ocean to Montreal was a regular trip. Montreal would be easy with a small transmitter and close enough from here. There are rapids that are not easy however not impossible. But perhaps too much for a sub. Since the Seaway project of the 1960s it is a moot point. You can get here from there easily now.
Anyway the sub story is fact. I have it here somewhere not that it matters. BTW I got to tour a Dutch Sub on my vacation to Holland. XYLs cousin took us to see it. Never expected that. It wasn't a 2 man though. Crew of 76 I believe is what he said. Nice radio room!
PM AM net 7 PM EDT Sunday on 3840kcs AM. I often read the mail but someone has a new SDR and everyone now has FMing (including his local radio station) or poor audio and I don't have the patience for that when running a 70 year old piece of gear. The SSB had no takers last time I listened which was about 3 weeks ago.
Monday (today) on 160M at *PM Joe (N3IBX) has a SSB or AM net listed 1.945kcs
Monday Wed and Friday on 3837 at 9:30 AM SSB only.

Done!
Just finished a QSO on the "Adapter" with WB4FDT "Pip" in Baltimore MD. 326 Miles ATCF and a decent RST.
Also tied to hide it in my work boot. No problem. Even without a sock stuffed in you would have to actually look inside to see it. Not needing to carry a tube must have been a huge advantage. Fun Build! Even more fun to use.

No, I had totally overlooked/forgotten about the St. Lawrence seaway,
and I'm not sure I ever realized it was navigable all the way to Lake
Ontario. My mistake.

No problem. I checked into it. Been navigable to Lake Ontario since the 1780s. By 1959 with the Seaway project it became navigable for "deep draft" ships as well. (now 26 ft deep at shallowest spot) My sister lives on the river on the NY side (Morristown NY) and large ships pass her dock all day long. However you got me thinking. Here in Belleville lives the man who did much of the development of the two man sports subs. He runs an aluminum foundry and has done some prototype manifold casting for me. I am going to visit him at the sport sub shop and ask if he thinks a old two man sub could sneak through a set of locks. These are the guys who did the sub treasure hunting for Fidel Castro a few years back. It will be interesting to hear what he says.
Anyway the lil rig works great. Doesnt seem to have any drawbacks . The slug tuned final will pull the Crystal up more kcs then a cap usually pulls them. I was operating as high as 7052 last night(on a 7050 rock). Usually one only gets a few kcs(25 to 50) of wiggle with a typical VXO. Will also have to sit down and draw the schematic so I don't forget what I built. Was a fun build though bit much more fun working WB4FDT. Also tried hiding it in my work boot. No problem! So it could be snuck in back in the day I think quite easily.
donVe3LYX
BTW someone was talking the other day about too much crystal current the other day. On this rig I used a receive type RF choke in parallel with the crystal to prevent that. Also was not uncommon to use a pilot lamp bulb in series for the same purpose

:>) Poor Mike! This too will pass. Would have been fun to work U
No Lou. I did not tonight. The band was fairly quiet but I stayed at it till 11:30. I believe I can eliminate the chirp with a minor modification. (By pass the indicator bulb after tune up) I am going to try and find a 1940s table radio to set it up with. I see them often in Antique shops. Probably even an early AC/DC set with a 50l6 would work well. I tried a bunch of different tubes last night. It really liked the 6y6gt however that isnt one that would normally be found in a home radio.
Speaking of tubes I have an old octal tube battery radio that has a 1C5E tube. I cannot find the pinout for that tube even on Vacuum tube museum. Anyone have it?
Also we were talking last week about the CMS set 4 pin socket. I made the crystal socket for this set exactly as I described in my post. I should have photographed it but I didn't. I used perfboard (Phenolic) to make it and an old wafer socket supplied the contacts.
I can get the rig to operate as high as 7052.9 on the 7050 crystal. I am surpised how well the slug tuned final works for that. Much better then a normal VXO capacitor and opposite. In fact I can get out of the way of W1AW enough to operate without interference by tuning the final slug. I am surprised by that. Enough that one crystal would be quite useable. However I need to find a 7020 FT 243 and perhaps a 7010. There is a net on 7052 sometimes and W1AW right below so the sooner I get away from them the better. Still It works as good as my breadboard 80M station. It is fun to run.

Whatever. I know from actual testing contrary to opinions that the real power loss could probably not be measured on conventional equipment as it is quite minor however this particular bulb only lit on long dahs and when it lights resistance changes the most causing a slight whoop at the first key down. I am out of the good old ones. Still a bulb is a very very effective tuning device and much easier to hide then a meter. Pip said slight chirp in his signal report. I take that as minor. Anyway it is gone now. Only used when tuning. Gives more stealth. Brought an old late 1930s battery radio (Octal 1 series tubes) up with a final tube that works in this adapter. Took pictures as we took the completely hidden adapter and antenna out of my shoes and pulled the tube, popped in the crystal and plugged in the set. Then I hooked up a hand made wooden CW key and antenna. Then XYL timed me. From when she said go to the radio back to normal and everything unhooked from the adapter and the crystal hidden in my pocket was exactly 30 seconds. I had figured perhaps a couple of minutes . I am liking it better every minute.

Seems high, but I suppose to build something cheaper means either having the parts in the junkbox or finding deals at a hamfest... which I have noticed over the last couple years is getting harder and harder.

The local hamfests used to be gold mines for parts. Now, nobody is bringing stuff like that and you really have to dig deep or get lucky. Things like variable caps, DC ammeters, standoffs, coil stock, etc.

Attachments: 1 described; binary payloads are missing from this source WARC

Here is one unrestored example of a radio from back in the day that will take this adapter. It took about three minutes to turn the set around on the table, remove the audio tube, plug the tube into the adapter and plug the adapter into the radio's tube socket, take crystal out of pocket and insert into adapter, attach hand made wooden CW key and clip antenna lead to ariel. All that would be left is turn on set, allow warm up and send away. I was talking to my brother. He has my Grandmother's old Radio. The only one she ever owned and it has a 7AC pinout final tube as well so we are going to try it on it when he returns from his trip in Monday. If it still works we will try the adapter and see if we cant get a QSO with someone. If you think Doesn't look like much. Doesn't look like a transmitter, in this case that is a good thing. XYL says it needs paint. She suggested a soft brown would make it even easier to hide. Would also make a good first rig.

No, All the adapter does is access B+ (pin 3 and Pin 8 for B- . 2 and 7 for heater of course but no grid (pin 5), no screen (pin 4). so there is no signal coming from the radio to the TX. Also i built an RF choke in the Bplus just to be sure and everything it well bypassed as well. I stole screen voltage from the plate in my usual fashion. (25K resistor by passed to grnd at both ends)
Funny you ask now. When I took the pictures that old radio wasn't functional but it was raining here and the XYL had a WI meeting so I went at it replacing all the rotted power cables (it is a battery radio) with some period correct wire I had here on an old lamp. I proofed the B+ to each tube. The switch B connection was not good (high resistance) so I resoldered it and it came into spec. (zero ohms) . I clip leaded the B battery circuit to my regens 90 volt pack and took a single D cell to run the 1.5 volt tubes figuring it would be good for a couple of minutes at least. Tuned the dial to 800 where our local radio station is and turned it on. Worked fine. So now the moment of truth. Up till now I had been running the Adapter on my light duty bench supply as all my power supplies are wired with octal socketry and the 7AC pinout anyway. Would it actually work especially with this set and a battery powered tube with the same pinout but directly heated.(1C5E) So I unplugged the tube, plugged in the adapter and put the tube in it. The key and Antenna were already hooked up as I have used the little rig a lot in the last few days. I pressed the key and heard it in the monitor receiver right away. Does it work as advertised? As a matter of fact yes.

You could, if you had the space in the box, add a 4PST switch for T/R - one pole to switch the screen circuit, one for the plate circuit, one for the grid circuit, and one for antenna switching. That way the tube would be in it's normal connection as an audio amp in the receive position of the switch, and would be your power oscillator in the other position. You could probably get away with leaving the cathode circuits for TX and RX connected in parallel, depending on the oscillator circuit.

In most, but not all communications receivers of the era, the Hi-Z headphone output is between the 1st audio and output stages, so you'd still have headphone receive without the above complications, anyway.

This discussion is only pertinent, of course if the "host" receiver is capable of receiving on the operating frequency, and has at least a BFO for receiving CW. I'm thinking at least a Hally Sky Buddy, for example.

25K sounds high - you're probably leaving some potential RF output power "on the table." If you don't mind, that's fine. But if it were me I'd fine-tune the value for the typical 6F6 or 6V6 at the applied voltage, measuring screen voltage and current while it was oscillating and tweeking the resistor so that your screen dissipation is just below the maximum spec. listed in the tube manual. The same resistor value would probably be close enough to work with other tubes/sets as well - such as your battery set.

Flying Aboard The Handley Page HP-42. Imperial Airways 1931 to 1939.

What flying was like around 80 years ago. No in flight-movies, no wi-fi connection and worse of all no pretty stewardesses, how did they make a go of this?

Flying the airlines in the thirties was a lot more fun than it is now. It was more leisurely and had more class. If people had serious money in the 1930s and travelled internationally, they may well have flown on one of these large (130 foot wingspan) Handley Page bi-plane aircraft, which were the mainstay of British Imperial Airways at the time. They carried 26 passengers in first class only, in three different compartments. The first class saloon, the bar and cocktail area, and the smoking section.

These machines were ubiquitous, extremely safe (no passenger in a HP-42 was ever killed in 10 years of international and domestic operations from 1930 until 1940), very comfortable in seating, leg room and service, hot meals were served on bone china with silver cutlery, free liquor flowed, overnights were in the very best hotels. There was no rush, no waiting in lines and everyone was well dressed.

Flying along at a few thousand feet, one could see, (down to the quality of the washing on the backyard clothes lines) every interesting feature passing below. At 95 to 100 mph. one also had time to look at the passing panorama. It took four days to a week (depending on headwinds and weather) to fly from London to Cape Town, South Africa by only flying about four hours a day, staying at the best hotels in Europe, Cairo, Khartoum and the Victoria Falls.

No airline passenger was ever killed in one of these machines - in 10 years of service. They flew all over the UK and Europe and down to South Africa on a regular basis. They also conducted regular services to India via many places en-route.

There were occasions, flying down to Cape Town, when the strong headwinds from the south reduced the ground speed to such an extent that the crew turned the machine around. They flew back to their point of departure and sat it out in the hotel.

The ac looks like the tail is going to fall off with the slightest bit of turbulence.

A 1930 flying magazine's view of the new HP-42 airliner. Note crew member as the radio operator.
The Bristol Jupiter engines were initially 450 hp and later bumped up to 550.

The crew. The Captain, almost certainly, would have flown in the First World War.

Imperial Airways advertisement of the day.

Khartoum , Sudan. Boarding for the flight south. Only one more overnight and then they will be taking in the sights of Lake Victoria.

There was only one class; First Class. This is the forward saloon. Note the gentleman's pith helmet in the rack. Airspeed indicator and altitude displays - as in modern jets - are on the bulkhead.

All engines running and the Captain not at the controls?

Cabin of a Handley Page HP-42. 1931. British Imperial Airways.

The cockpit of a Handley Page HP-42 airliner. London, 1931. No powered controls here.

HP-42 airliner ready for a night flight. London's Croydon aerodrome, 1931.

HP-42s at Croydon. Part of the Co-Pilot's duties was to stow the flag before take-off. The Bristol Jupiter engines are warming up.

HP-42 over London. Cruise speed was 100 mph or 87 knots. Maximum speed was 120mph or 104knots.
.

A KLM DC-2 and an Imperial Airways HP-42 at Croydon, 1933.

Imperial Airways at Cairo. 1932. Note the refueling equipment, including the ladders resting on the upper engines. Note, also, the modest terminal building.

RAF Hendon Airport, London, 1937. Royalty arrives. King George VI, centre, and Queen Elizabeth on aircraft's steps.

13920. Re: [AWA Group] Adapter set

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-15 01:23:10 UTC
From: dulmagedon@...
Topic: 13891 Message: 13920

Well it isn't my idea. It was used at the first of German intelligence gathering. I searched as much as I could find. Found they were hand built by former ham operators and not necessarily alike in circuit although function is the same. When I look at the tubes and consder the host sets that will take it as a striaght plug in it amazes me. For instance any set with a final , 1C5E,6W6 6F6 6y6 6V6 6L6 6K6 1622, 12L6 25L6, 35L6 50L6 50C6 and that is probably just the main ones I realized the number of sets that this adapter would work in is huge. I 1936 to 1941 one would have little trouble finding a host set. I am hesitant to optimize for the good tubes because I want to maintain the versatility and power out is suffcient to be practical as proved by the contact with "Pip' WB4FDT. 25K is sort of my working standard for these beam power tubes. However if one so desired it could be done. The RX presents several problems as you have addressed. I don't think they worried about receiving but simply delivered the report using the specified freq or crystal. Since the mission did not change it was possible to operate this way. I am surprised it works as well as it does. I intend to research further. Thomas gave me some reading hints. As did Jim K.(KRIS) There was also a movie Kontact but so far I can't find a source for it.
I think the strong point of the adapter set is its ability to be used without any changes on a large number of home radios or amplifiers. One can be on the air in a matter of minutes. No need to bring a tube or worry about correct power supply or connections. Plug n play if you will.
I am looking forward to trying it on my brothers radio he got from Grandma. He says it has a 50L6 (Joe has dealt with him (Dan) before) Interesting Grandma's parents came to Canada from Germany just before WW1. Grandma still spoke German often even though she was born here. She taught me to count in it. However she raised a brood of loyal Canadians . Three boys joined up and spent the war overseas welding up holes in tanks etc. And two daughters were successful in the RCAF (Mom and Aunt May) Uncle Mark and his crew of fitters/ welders captured a German tank during the war. Uncle Mark brought home the NAzi flag from it when he returned at the end of the WAR. I heard the story many times but Grandma said it was dirty and smelly. So she washed it and hung it on the clothline in Kitchener Ontario. The neighbours went beserk. And in case you didn't know Kitchener was before the war called Berlin Ontario. So it is only fitting her radio gets the test. Dan says it may need new electrolytics but I have them in stock and ready to go in.
BTW Mark Daniells Jr, Uncle Mark's son works for Car 16 Greg Biffle in nascar if any of you are nascar fans.

The receive thing is an interesting thought. It could certainly be done however many sets back then were as you mentioned already Shortwave. As far as earphones the signal is already delivered to the audio final socket at pin 5 (grid) so a pair of hi impedance phones from there to Grd will get you that. Now the BFO thing. My No 19 set which I have used to talk to you several times has MCW which would send CW without needed a BFO rx. I often wondered why they had that on some radios but perhaps that is why. Could be received on a regular household shortwave set. I don't know of German radios had that option on any of their transmitters or not but it would work fine. There is another possiblity but I want to fool with it a bit before I mis-speak. I have my eye open for a late 1930s early 1940s working or repairable household wooden radio with shortwave and will try a couple of things there when I get one. My goal is to set the adapter up as would have been back then as a regular station in my vintage shack and see how that would have faired.
BTW I would like sometime to try the MCW function on my No 19 so if anyone volunteers to listen on an AM RX I would give it a quick shot.

GM Don,
? ? ? ? ? ? ? ?I would hardly be the best one to do a radio check with on MCW with your Wireless Set No 19, but I would be willing to give it a try nonetheless. The distance between us would definitely make it a challenge!

Regarding the condition of my own "Northern Electric" WS No. 19 MkIII, I have yet to find the time to pull it out and debug it to make it operational again as originally stated some time ago. I still have it slated to receive one of those "Roundtuit" things that make all good things happen. At that time I would love to have a W.S. No 19 to W.S. No 19 QSO with you as stated sometime ago.?

I am counting on that 19 to 19 QSO Joe. Sometime before we hit the sod.
As for the MCW test what time of day and freq would work for you?
I am thinking about 9PM on 7105kcs. I would keep it real short . Just to see if it is possible.
So let me know what time and freq works for you if not this one.

ARRL/QST published a transmitter project along these lines in the Dec '46 issue. It was a 6L6 or 6V6 oscillator powered from the rcvr AF socket and using the rcvr 6L6/6V6 AF output tube. The claim was that many SW rcvrs of the time took the headphone output before the final AF tube so when using headphones the tube is not missed.

The ARRL version is built up using slatboard/popsickle stick chassis like this one: http://www.nt9k.com/image/slatboarda.jpg http://www.nt9k.com/image/slatboarda.jpg rather than a metal chassis.

To go further. I knew somewhere in my memory I had read you could steal from a RX and borrow the tube so when I saw and read of the adapter sets I knew it should work. After you posted this I dug out an old 1948 ARRL handbook to see if that is where I once saw it. It was. In fact i suspect it is the same article your refer to. It doesn't say a lot about it but does offer it as a practical method of power and mentions the earphone thing. All in one paragraph. Anyway that should lay to rest the question of if it will work (which always confuses me anyway. When something IS working why do folks question IF it will work?) Anyway, aside from any clandestine ops the basic concept would also have made a great "first RIG". I am now on the prowl for a 1930s Broadcast with SW set with a suitable output tube.(7AC or 7S pinout) The radio I tested it on yesterday is a CGE H4B made in 1938 so it is period correct. It has been for me a very interesting project. Thanks for the info. donVe3LYX

I was driving by an antique shop and stopped in just in case they had a SW old wooden radio. They did not but saw something strange that I have been thinking about ever since. A fish hook and fishing line would around a thin piece of wood except the fishing line was solid copper and there was quite a length of it. Maybe that isnt unusual although when younger I used to do a lot of that type of fishing and I never saw solid copper fishing line back then. Whatever the case may be would be a great way to hide a very good long wire antenna. The store also had some Mil Amp meters. Two in particular which were 0 to 10ma and one case mounted which was 0 to 150ma. I didn't have my "mad money" (they don't do plastic) with me but it is only a few minutes away so I will go back and get them. I was thinking about Lou's comment that the stuff is getting harder to come by so I think the meters would be worth having. Price was right. The fishing line and hook will go to my Spy station set up.

Does it make any difference in a loose-coupled Hartley if I couple the antenna coil at the plate end vs. the grid end? I don't think it does since the magnetic field should be symmetrical, but I thought I would ask. (I'm keeping the B+ off the coil with a blocking cap.)
Thanks!

With link coupling the idea is to have all inductive coupling with as-little-as-possible capacitive coupling. This is why if there is an RF "cold" side of the tank coil, that is where the coupling link is usually placed. In the case of the Hartley in it's usual transmitter configuration neither end of the coil is "cold" for RF*, so to minimize capacitive coupling you'd want to choose the end with the lower RF voltage. I'd test both ends of the tank coil with a neon bulb and choose the end where the neon bulb is dimmer.

*In local oscillator and regenerative receiver applications it is typical to have the plate side of the tank inductor grounded, with the cathode tap and grid side at RF. I have not seen this configuration for transmitters, where it is common to have the cathode tap at RF ground (if not DC ground as well). I don't know if there is a good reason for this convention (?). If a tube with a directly-heated cathode is used, doing this would require RF chokes in each filament lead to be able to "float" the cathode circuit at RF.

73,
-Larry/NE1S

I have a Howard 436A on my bench right now - I was getting it ready to put it on ebay. (I'm going on 78 and I promised my good wife that I wouldn't leave her with a bunch of boatanchor radios to get rid of when I kick the bucket.) It might be the "1930s Broadcast with SW set with a suitable output tube" that you are looking for. The tube lineup is a 6SK7 RF, 6SA7 converter, 6SK7 IF amp (one, with "iron core" transformers), 6SQ7 detector, AVC, and first audio, 6J5 bfo, 6K6 audio output (7S pinout), 6H6 noise limiter, 6J5 bfo, and 5Y3G rectifier. It tunes from .54 to 43 MHz in four bands, and it has uncalibrated bandspread. It has an internal speaker, about 6", mounted in the top of the cabinet. When I first got it I added an IF Gain control which made it much easier to use on CW and SSB - it originally came with only an audio gain control and the RF and IF stages ran with maximum gain all the time with the AVC turned off. I just finished aligning it. It works well on the lower three bands and OK on the top band, but it is less sensitive there than on the lower bands - no big surprise. All of the tubes test good on my Hickok tester - I replaced the original 6SQ7 with a NOS one from AES. The headphone jack is fed from the output transformer, but if you wanted to use the RX with your Adaptor Set you could rewire it to take headphone output from the 6SQ7 stage. The cabinet finish is "rough." Someone masked off the control markings and the Howard logo and painted the cabinet gray. You could strip it if you want, and I think you can find a set of control markings on the internet for a Howard 436A. Also there is a vertical crack in the dial "glass." It's a piece of polystyrene and I just painted a little MRK over the crack which seems to have wicked into it and partially fused it. Raymond Moore's book, Communications Receivers, dates it to 1941 - 42.

If it sounds interesting I can send you some pictures. It's currently out of the cabinet, so I can show you what the chassis looks like.

Andy, I use often an RF sniffer to find the sweet spot. A loop of wire feeding a Christmas tree bulb or pilot lamp. I install it both end or near the middle and move it around to get the best glow. Sometimes I am surprised. It leaves no question though where the best spot is and takes only a couple of minutes.

I appreciate the offer. I wish to have a stock unmodified set if possible. As a spy would have found in his boarding house. That was my plan anyway. The other big difficulty is shipping. I see them often here at antique or junk shops. I let a few get by this year even as until this last week or so I had no need of one. However I am saving your email in case I come up dry. I passed one up at an antique store north of Belleville a few days before we went to Holland. The fellow was down to $50 on it. I just went there today. He wasn't there but his wife said they sold it on the weekend. I know where there is a floor model I can get for asking although I may have to fix one of his to get it but I am hoping for a tombstone model. However yours would work for sure.
I am thinking.....

I borrowed my Grandma's old table radio from my brother who she gave it to. I had to recap the PSU but it is a typical big tube AC/ DC set. Final is a 50L6 so fter fixing it and making sure it would work good for Dan I popped the final into the adapter set and plugged the adapter set into Grannys Addison .9Addison is a Canadian make from back then. It is so Canadian it even had original Robertson screws, eh?. I had to retune the final on the adapter about a 1/2 turn from what the 6v6 liked but it took off and had good power and good sound on the monitor. So I have now had a 1C5E (1.5 volt tube) A 6v6 (6 volt tube) and a 50L6 9 (a 50 volt tube) all working on the same adapter with no mods whatsoever to the host set. No worries about voltage as it is automatically right but just minor tweak in the tank circuit to compensate for differences in the tubes. Dan has a big floor model late thirties short wave set. It quit a few years ago. I will take a peak at it. If it isn't a transformer but something reasonable I will fix it and see if I can manage a QSO using it, my pre final headphone jack on the adapter set.

Adam and Andy would be a handful. Actually in my family it is
Ron, Don, Dave & Dan, Rae and Ruth. Dave and Dan are twins and never to my recollection got in any trouble.
Rae was the youngest for a long time and lived a charmed life. Ruth of course is perfect being much younger then the rest of us and the only girl. Ron was the fair haired boy so in reality only one got yelled at on a regular basis and I think you know him. Probably why I still have such a short fuse.
Dan and Joe N3IBX have had some contact a few years back as they both have the same SW RX in their collections.

13940. Where to put the plate choke?

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-22 12:29:54 UTC
From: aflowers@frontiernet.net
Topic: 13940 Message: 13940

I'm trying to figure out where to mount the RFC on the B+ in a shunt-fed Hartley under 10 MHz.
I think in general its better to have the RFC mounted relatively close to the plate connection on the tube. The design I'm looking at has the plate current meter between this RFC and the tube and given the physical layout this means that there would be several inches of wire between the RFC an the plate of the oscillator tube. I'm guessing I should prefer to have the RFC close to the tube to keep RF from modulating the DC plate supply.
Can anyone offer any advice about the physical location of the RFC?
Thanks,
Andy K0SM/2

Andy, I agree that the RFC should be as close to the tube plate
connection as possible. Also, when you said the design you are looking
at has the plate current meter between this RFC and the tube. I think
you mean physically, and not electrically, since the latter would be an
obvious design error and generally bad practice. Physically is bad enough.

Thanks Larry,
Indeed, the schematic I'm looking at has the meter between the RFC and the plate, electrically. I probably shouldn't surprise us that bad designs got published in the early 20's when this was all new everyone. Navigating that is part of the fun. The old hot-wire ammeters might have been more forgiving to this sort of thing, and you could probably get away with more at 1700 KHz than you could at "modern shortwave". Still, I'll do it "right" since its keeping in the spirit and practice of the time.

As long as you don't have any questions for the seller....

I was looking at another of this seller's items and forwarded a question via the official Ebay mechanism three (3) times over several days. No answer. Quite irritating. Looking at some old feedback, seems to be how this person works. I'll go on record and say this seller is a dead beat and should be yanked off of Ebay. The descriptions are even generic, inaccurate, and probably some statements a lie:

Comes with a power cord and was hooked up and working when I removed it.

Verbatim on several of the listings. How does he (she or it) know it was working.... doesn't even identify any of the stuff by it's proper name.

Fortunately, I found what I needed (HRO IF/BFO cans) from another source, but even thought of a spite bid/win just to give this loser negative feedback..... think I better go build something.....

13948. Motorboating in oscillator

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-24 13:36:33 UTC
From: aflowers@frontiernet.net
Topic: 13948 Message: 13948

Hi again,
I'm working on a self-excited Hartley transmitter and I'm having a problem that I've not encountered before. First, I'm attempting to key the rig by keying the grid-leak resistor. This is the same keying method in all the TX circuits published in the 1921 RCA Apparatus Catalog. I think of it as very primitive grid block keying.
The problem is this: I'm getting some motorboating when the key is up (i.e., the grid resistor is effectively open). The effect is a popping in the 1-10Hz rate in the monitor receiver, as if the oscillator is trying to start. I can tune it with the tuning capacitor and it makes for a neat spotting function in that sense, but I don't like RF coming out of the rig when the key is up! The motorboating gets faster with higher plate voltage.
I'm sure there is a reason this keying method fell out of favor and this would probably go away if I switched to cathode keying, but I don't want to give up easily. Perhaps someone has been down this path before and can offer some things to try?
Thanks,
Andy K0SM/2

I don't see how. With grid block keying, one applies enough of a negative bias voltage to the control grid to cut off any plate current. If you merely open the grid circuit for DC, effectively floating the grid, I don't see how this can do anything but make the DC plate current and power dissipation soar to the point where it's dangerous for the tube (as well as stop any oscillation of the circuit, if the RF path to the grid is also interrupted). If someone has a better understanding, perhaps they can explain how this won't happen.

Could you provide the exact circuit, including the point where you're keying it? I have some ideas to explain how it could happen, but seeing the circuit would confirm whether I'm on the right track or not.

Not me. I've never used anything but cathode keying, which is both elegant and effective, for these old circuits.

first you are using a directly heated tube I would guess. That is the indirect origin of the problem. 2nd you may also be using a ground to actual ground which with that set up can cause this. buop buop buop buop .
First thng to try is disconnect the ground to ground and see does it make any difference in any way. That will give you a clue. If it improves move your antenna link ground to the same spot as your cold side tuning coil and it may cure it while still allowing the rig to function and don't bother with the real earth ground.
3rdly How is your grid leak resistor installed? In series with the grid coil connection or to the B- direct?
Cathode keying while perhaps not ideal is very practical for directly heated tubes.An indirectly heated tube would most likely not have the problem. So has been my experience. I have dealt with this in my building and not too long ago the last time. So when I run into it this is what I do. We can discuss all day why and how or you can take a few minutes and try each . Anyway you asked has anyone --- yup and this is what I do each time . So far so good.

Yes, this is all directly-heated, parallel 01A's until I have confidence that the circuit is doing what it should and I'm not going to blow up something more valuable.
I wired up for tried and true cathode keying and it sounds decent--with just the key on the B- to the supply. I'm using bench supplies for the filament and plate, so there is no center tap to key.
Still, I'd like to know more about the grid-leak keying in the old RCA catalog. I'm watching the plate current at all times and didn't see anything unusual--there was a little current draw consistent with the motorboating, all well under key-down current...of course, I don't have anything monitoring the grid current specifically.
FWIW, my 1924 ICS Radio Handbook says the only acceptable way to key a CW transmitter is by shorting keying some extra turns in the tank to ground to move the frequency a few meters--anything else will result in a ragged wave. There do seem to be some differing opinions in the early 20's!

Not for that reason but I often split the B- feed through a pair of low value resistors. Some old timers used pilot lamp bulbs for this. Most common I use are 10 ohm. One to each side of the heater connection. B- comes in the centre. This circuit shown feeds one side direct. It works but not the best idea I think. If the tube(s) was biased to cut off with key up and that resistor bypassed by the key in keying allowing the osc to function properly then no current would flow key up and no motorboating could occur. However here in this circuit that is not the case. The grid DC is being turned on and off but AC (RF) can still flow (cap). If the tube is capable of self bias to any extent then it will want to run anyway. Not every article has actual testing. Sometimes things appear in magazines that are not right, even today. I know you are committed to making this work and share your frustration that it is being "stupid". Give it you best shot. If it doesn't go set it aside for a bit and try again later. But you already know all that. I realize this is not UR first rodeo. So I wish you all the best with it.
donVe3LYX
BTW I have read several articles in old OTB etc on builds from old mag articles. Not good many times. In fact some would not work at all. You have to know someone wrote it all down but probably ran out of time to do it and test it but printed it anyway because what the He--- they were sure it would work. Still happens today. Perhaps not likely, if you want to think that, but certainly not an impossible situation.

13954. Adapter Spy Set Adventures

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-07-25 16:34:39 UTC
From: dulmagedon@...
Topic: 13954 Message: 13954

We talked awhile back about listening or receiving on the host set with a set of Hi Imp earphones stealing the signal from before the final tube. So I wired up a phone jack to pin 5 and pin 8 of the adapter plug. (output tube grid pin hole, (unused for the adapter TX) and essentially ground) with the adapter plugged in and in operating mode (key up of course) Does it supply normal audio to the phones from the audio driver circuit? YES. Is it independent of transmitter tuning ? YES. Works perfectly . Tried it on a CGE 1938 table radio. Volume is excellent for Earphone use and the radio doesn't know any different . So now how about no BFO problem. It occurred to me that some of my military radios have MCW as well as CW. MCW which is basically AM anyway does not require a BFO. Thinking that might be too far a reach I searched military collector sites I belong to asking did German transmitters have MCW (A2) function. Never got an answer but did stumble on to a good communications museum site in Moscow. So I went through the list in their collection. Two radios, one of which is the German equivalent perhaps of my No 19 set had that function. In fact it had ONLY A2 (MCW) and A3 (R/T). No A1(CW) function setting. So that seals it for me . Plausable , possible and most likely so. Next is a actual test QSO. An old friend offered to loan me his Grandfathers 1939 Broadcast/SW radio for the test. However in reality if the set hears AM then it will hear MCW too. That we already know so it will be more for fun perhaps . Anyway, this adventure has been most interesting. I am still playing around 7051 kcs when I get a chance. And on the bright side. Three late 1930s radios got repaired and functioning so I could use them testing that otherwise would have been gathering dust. A fourth is well on it way back , just awaiting a 6e5 magic eye so that is also a good thing. So the similar design in the old QST that was mentioned is I would say based on my experiences with this one probably a rather good design.

OK, here's one attempt to explain what you're observing. The may be circuit is acting as superregen oscillator during key-up, but with a very low interruption frequency. For this we would need a very long time constant - for the purpose of argument, let's say 1/2 second. When the key is open, you might think the grid-leak resistance is infinite. It isn't, although it could be a very high value. There is always leakage, somewhere. One strong suspect might be an old bakelite tube base using wood flour as filler, leaking from grid to filament (as well as grid to plate and plate to filament). I don't know the value of C3, but, again for the sake of argument, let me assume 250pF, a typical value. To result in a time constant of 0.5 second, the leakage resistance key-up wound have to be 2 teraohms (2000 megohms). Certainly possible, IMHO.

Don,

The Hallicrafters S-38 series and the National SW-54 did not have a BFO as such, they caused their single IF stage to oscillate in order to receive CW. I just looked at the schematic of the S-38A on BAMA, and the CW function is actuated with just one spdt switch and a couple of "wiring" capacitors. The swinger of the switch is attached to ground. There are two "wiring capacitors," one attached from the 12SK7 IF amp control grid to one contact of the switch, marked "AM", and the other wiring capacitor connected from the plate of that same 12SK7 to that "AM" switch contact. The other switch contact, marked "CW", is attached through a 470 ohm resistor, to the AVC line. When the switch is in the AM position, the feedback path from plate to grid is interrupted by grounding the center junction of the two capacitors, and the normal AVC voltage is applied to the control grid of the IF amplifier tube. When the switch is in the CW position, the feedback path from plate to grid is activated causing the IF stage to oscillate, and the AVC line is disabled by grounding it through the 470 ohm resistor.

You might try this same trick to add a BFO function to one of your receivers. The "wiring capacitors" are probably just pieces of hook-up wire twisted together for a short length, probably less than an inch. A little experimentation should let you arrive at some satisfactory values.

Larry,
I was thinking along the same lines--leakage in the 10's or 100's of megaohms could do it. I once observed something similar in my old 27 Hartley when I put a 20M in instead of a 20K by mistake--key down had a random sputtering effect as if there wasn't a enough Brownian motion to the kick the thing off. I might have something like that going on in the key-up state. Different tubes did sound different.
I think your theory about the tube base is a good one, since these circuits assumed a ceramic base UV202 or UV203 and likely leaked less than the cheaper bakelite bases. Could it be that keying the grid leak relies on insulating materials in the tubes and sockets? I am using the RCA ceramic sockets, but my mistake could be in using a tube made after 1925!
Maybe I'll try it again with some brass base UV201's, but before I plug one of those in I would like enough understanding of the fault conditions of the circuit. I don't like the idea that melting the plate might rely on gigaohm levels of insulation in my tube socket and panel material...
FWIW, I fabricated the 250pf grid condenser and a ~1200pf plate blocking condenser following a 1924 "Radio" article. I couldn't measure any leakage through them, but that doesn't mean it isn't there in the values we're talking about--the terminals are connected by 3x4cm square of 3/16" bakelite and have 25 mils of mica between the plates with generous overlape at the edges.
This all works just dandy with cathode keying, so that's probably what I'll end up with in the finished product.

Thanks fellows. I had wondered and figured it was possible with little effort to effect. I had mistakenly thought perhaps a slight mistune of one IF might make CW copy possible but this is a much better deal. However when I discovered that some De sender sets had A2 I relaxed a bit. I have been considering moving a AM table radio to 160M and using this Tx method like the adapter set for a bare bones 1930s style 160M station. But was thinking it wouldnt be practical because no BFO. That little trick would allow me to implement it on the old table radio. Gimmick Capacitors: I can still recall my Dad at the dining room table the night he helped me quit fooling around and get my first regen built. (12ax7) He showed me how to make a gimmick capacitor that night with two pieces of hook up wire and warned me about over coupling the antenna to a regen. (As well as a lecture on the evils of too much antenna on a regen. I can still remember the thrill when signals came into the phones for the first time.)
BTW as an asude . We were talking a bit about Great Lakes waterways a few days back. Did the trip through these today. Pretty impressive engineering. 65 ft lift in about 4 to 5 minutes.https://en.wikipedia.org/wiki/Peterborough_Lift_Lock

Lou reminded me of an article from the July 1921 QST where a self-rectified circuit was used to win a "QRP construction contest" of sorts at the Hartford ARC:

"Mr. Whittier uses the key in series with the grid leak, but in this set such operation caused a continual "gurgle" when the key was idle which was very distressing for local work, altho (sic) it disappeared at a distance. To overcome this the key is now placed at the bottom of the inductance as shown."

It seems I have also stumbled upon the "gurgle". The surefire solution is to put the key elsewhere and probably explains why this method keying method had a short life.

OK, let me see if I understood that. On the If amp tube I add two gimmick caps. One around the grid lead and one around the plate lead. No connection. Just a gimmick caps capacitively coupled. The other end of both these gimmick caps is soldered to one terminal of the Am Cw switch. The other end of the AM CW switch (other position) is soldered to a 470 ohm resisitor connected to the AVC supply line. The switch wiper is grounded. So In AM mode the AVC is normal and the 470 ohm resitsor floats (no connection) The gimmick capacitors picked up signals which would be quite small are returned to ground through the switch rendering them ineffective while in reality having little effect on the overall operations as values would be small. and no real HARD connection exists. In CW mode the AVC line is grounded rendering the AVC function inoperable (why?)and the gimmick caps couple plate and grid capacitively however the actual value of coupling is enough to rpoduce some feedback causing oscillation which when combined with the incoming signal from the mixer causes the signal to be heard as an audible beep like a BFO does. I may not have said it technically for which I beg forgiveness perfect but that aside , is that the basic idea? donVe3LYX

Don,

Yes, you have the "bfo" connections correct. I'd encourage you to go to the BAMA manual connection and have a look at the S-38A manual and schematic to verify this information. You asked why the AVC line needs to be disabled (grounded) during CW operation. That's because the high signal level presented to the detector by the oscillation in the IF stage would create a very large, negative bias on the AVC line which would cut the gain in the IF stage way back. You need to defeat that by grounding the AVC line.

This type of "bfo" was used in all of the S-38's from the A model onward and also in the National SW-54. It works well enough for an awful lot of Novices in the 50s and 60s to work a lot of CW. Give it a try.

73,

Jim

Thanks Jim, I intend. Already have a suitable project underway where it will serve perfectly. BTW I sat downfor some light reading last night. I hav a small box of OLD OTBs and was reading an article on Receivers then noticed your name and an introduction about you at the top of the page. You write well. (I am a mag writer for over 23 years so this is a professional opinion)Easy to follow. Thanks for the hint here.
On another vein , Went to an antique flea market today in Kingston. Just as I was leaving empty handed I noticed a CW key in one of the cabinets. I bought it for about $50 US ($65 Can) An NOS unused never made a spark J-38 key on mounted on a display base. Perhaps that is no big deal but I was happy to have it. Must have been a display model or something. Not a mark or bit of ware on it anyway. I am sure I am the first to open the shorting switch. I think Mike is the key guy here. Should I smile or cry?
Thanks again for the tip.

Everyone,

As net control (by default) I've made an "executive decision" that the Monday night AWA top-band net will take a summer vacation until after Labor Day. Participation has been meager this summer, and summer conditions, QRN, etc. have made it difficult to copy the more distant stations that have checked in.

That's not to say I won't throw out my callsign on 1945KHz LSB around 8PM EDT on Mondays, and maybe I'll run into some of you when I do. But I'm not going to make a firm commitment to be there as I do when the net is running.

After Labor Day we will resume the "formal" net (such as it is) on 1945KHZ LSB at 8PM Eastern on Mondays.

Hope everyone has a great August, and for those going to the Convention, I hope you have a wonderful time there.

73,
-Larry/NE1S

Don –

I am sure this will be easier to use than your wooden key, HI. The J-38 is probably the most common key around as millions must have been made by numerous manufacturers during WWII. The base was part of the key. Enjoy & 73 – Mike

What I needed it for was my second last project the Weskit inspired Trncver I have to close the key on RX and I wanted a key with a shorting bar as despite having about 8 keys not one had that option except my 1923 vibroplex. I just didnt expect to find an unused one like this. Anyway it isn't unused anymore. It does what I wanted it for so I am happy with that. As to your comment? Not even close. It is highly unlikely a metal key can ever match the feel , "stay with you ness" and smoothness of a wooden spring key. They are alive it seems. Course no one knows that as there is only one manufacturer. Some old grumpy fiddle maker in Ameliasburgh Ontario and the beggar is keeping them all for hisself :>) . (And he don't sell none of his fiddles either.)

Cool find! I've got a couple of 7-tube homebrew superhets with adjustable regeneration in the mixer. I think they are pretty much the same circuit between them, but the physical implementations (layout, parts used) are different.

I'm guessing it does not have a regenerative detector due to the BFO transformer that is clearly visible with its tuning knob on top.

I'd sure like to see a schematic diagram of this set, and it should be fairly easy to trace out with all that squared up wiring. And, what are all those toggle switches for???

Hello Roger,
? ? ? ? ? ? ? ? ?Many thanks for both pics of the Utah Jr. I saw the one of the front of it before and have to comment on the fantastic black crackle paint job you have it. I'm curious, did you have it powder coated? It looks stupendous! I hope you still have it so you can enjoy it once in a while at the very least. I also like all the round style crapstals you have for it. Are they Blileys? Just curious. Are they style AX-1 or "X" cut jobs? I would think an X cut xtal could withstand the grid current from the 6L6, which are inheritently hard on crystals.?

On to pic #2, which I've never seen before. Wowzers did you do a professional job on that supply! The wire looks perfectly loomed and I noticed you used two "miniature" type tubes, probably a 0A2 and a rectifier? Maybe not. I'm curious, what tubes are they? How does it perform on the air? I betcha you don't even have any keyclicks with the VR tube in the circuit.?

I don't know which I like more, the pic of the front of the Jr or it's power supply? Both are works of art as far as I think anyway.

I'll have a 1625 out to you and will send you a confirming email when it ships. I just have to find it and shouldn't have any trouble doing so.?

Thanks again for the pics.

Best regards,
Joe

Steve - I'll wager this could be a circuit from the Jones Radio Handbook since it seemed to dominate the western ham radio scene. I have a few of them and can check for something if you like.

I have the 1940 Radio Handbook. There is a 3 tuber and a 5 tuber superhet design with controllable regeneration. In the 1943 ARRL handbook is what is described as a 3 tube superhet but on page 202 and 203 there is section "Adding an audio stage to the three tube superhet." making it a four tuber .Tube layout is 6k8, 6sk7 6c8g and 6f6.

This did not work out like I'd hoped. After finding the rig and posting the pics Saturday, I did not purchase it until I had some time to research it a bit and see what feedback I'd get from the Group. My intent was to go back Sunday and make the purchase but they were closed. Unfortunately, we had to leave early today to get back home (an 8-hour drive). I may call them tomorrow to ask a few questions about the rig.

Thanks for all the comments gang,

Steve

I feel your pain! I left one in an antique store a couple of hours away. A Sparton Am broadcast/shortwave 1939-1842 approx) that quite frankly looked brand new except for dust. Must have never seen sunlight. The fellow was even willing to wiggle on the price but I whimped out having just bought the j-38 key which was over half my radio budget for the month. Today I sold my spare No 19 Wireless set to a fellow restoring an armed 1943 Jeep. (Machine gun through windsheild) It already had the PSU wiring still in it for the No 19 set. Display only so he is happy. And my excuse "cheep cheep cheap" is gone. Now I hope the radio is still there at the agreed on price when I get back there later this week. I want to use it for my Adapter Spy station set up. Hope you are successful in getting this one as well.

I read that agents sometimes used fake outlet boxes to hide things in the wall so I got a old early 2 prong type wall socket and plate from a friends early farmhouse and installed it after minor surgery on place of the smooth steel cover. This set in the wall could be removed easily but the transmitter device could be stored safely in plain site. I intend to make a small section of wall and baseboard for my display. Still have not got a SW version radio to try yet.

Today at an antique shop I bought a Stromberg Carlson model 61 wooden broadcast receiver with two shortwave bands (1500 to 3500kcs and 5.6 to 16 mcs) It doesn't work but doesn't smell smokey. It has a 6f6 final which I promptly tested in the adapter set with positive results. No decent voltage on pin 3 or 4 (plate and screen) so I suspect no hi voltage anywhere although set is still in its cabinet. I am not sure but suspect they used the speaker magnetic coil for a PS choke (because I would if I had built one back then) I don't know if that is right but live in hope that may be the trouble as the speaker is almost toast anyway. Otherwise I may be into a transformer. Decent set though. Even has a RF amp. I am in $30 so figured I had nothing to lose at that price. Tubes are easily worth that. I found a schematic and quick test sheet however should not need that anyway with a schematic.
Hopefully I can get it up and running by subbing a filter choke and normal speaker of which I have both.
Vintage is 1935/1936 so is period correct for the adapter set project.

Book came this afternoon. Just finished it. Good book. Well written and fast moving. Covers in detail day to day life of Allied spies living in their native Norway and operating daily sometimes for hours a clandestine radio station sending Morse traffic with shipping and weather info mainly. Confirms many suspicious I had about what may have gone on here before the war actually started. Not much technical info. In photos appears to be a parset but near the end he refers to a new American transmitter but no detail given. He received his training over here not that far away. Doesn't give too many details , just near Toronto. (Which is how we describe where we live when we are in Europe) Anyway a good book.. Thanks Tom for suggesting it. Someday I hope to sit down over wurst mit spaetzle and discuss it further.

Hello Don!

Great you got this book! The author, Oluf Reed Olsen, was also Radio amateur. After the war, they made a movie about the resistance work in Norway, and Oluf became an actor. The film was on youtube, but I can☐t find the link anymore in my mess.

I think spy activity in WW2 must not only be regarded from the technical side. You must know the stories, the circumstances as well. After reading some books, you dim the light and start working a paraset. With every dit, the two bulbs illuminate, and you run the next QSO with a very special feeling.

BTW: The Norwegians had to give away all their broadcast receivers. They were dismantled in Norway, and the parts were used for the war effort. Some Norwegians working in the workshop where they dismanteled the receivers took away special parts. They were used to build the resistance receiver ☐Lisbeth☐ or the suitcase receiver/transmitter set ☐Olga☐. Futher, Willi Simonsen developed the receiver ☐Sweetheart☐ in the exile. 6000 were bought from the Norwegian exile government and parachuted to Norway. It is a nice project, and parts are easy to find. The receiver works great!

I saw reference to the film Kontakt but so far haven't found it on DVD.
Yes, Although I don't have a paraset I do know the feeling when an old design starts to glow and a contact is made.
Today I was off on another adventure. I stumbled onto a reference about Cootie CW Keys. I must have led a sheltered life because I had never heard the term once in my life. Made by early telegraphers to relieve Glass Arm syndrome, main ingredient a broken hacksaw blade. So last night and today I made one. I had it up and working with clip wires and realized with a rather minor addition I could make it self complete the dahs. So after a bit of experimentation to be sure I was right I added what was needed. It works perfectly. Basically just the opposite of my vibroplex which self completes dits. I built it to operate like my other keyers so I wont get confused. Dahs to the right, dits left. Now to take it apart and make it pretty.

That☐s it! You can use normal single arm or 2-arm paddles for a first try. Make an adapter, where the two contacts (dash and dot) are connected together and hook it directly to the staight key input of the TRX, without any electronics. There is a sideswiper net in Europe. Keying sounds good! And: You are still ☐solid state free☐!

I had fun testing it.

Tom

Yes I see. I had never heard the "cootie" term before. Mine was manual for about ten minutes. Now it makes the dahs semi automatically. It was just too easy to do I couldn't resist.

Tom, you brought up a point I had wondered about. Since discovering info and building (and using) an adapter set I found it so practical and easy to set up and get on the air I wondered why it was ever replaced. It didn't occur to me that many countries would have had to surrender their home radios so the adapter would be useless there. No host radio to plug it into. It certainly has enough power for decent communication on any of the tubes I have tried it on and that is now about 6 or 7. So I now understand that while it would have been very practical here as our sets were not confiscated other places it was not so. The only solution would be a stand alone set. I may build a parset or similar rig replica. I have gotten interested also in the Flying Doctor radios designed by young Alf Traeger in around 1928. I see once he went out on his own after his helper moved he rebuilt all of the six sets, particularly in the receive section. Having built and use and am using several regens (currently 8 running here)when I saw what he changed I understood completely why. Regens are often ruined by over complication. The intention is always good and is based on the idea that with only one or two tubes it needs all the help it can get however that is not the case. A good regen is more then capable of holding it own against a modern set as far as sensitivty goes. In fact I have been testing just that the last few days with the regen section of my so called weskit style transceiver. Normally when operating my AWA style rigs I monitor in my shack for back up on a DX394 digital rx. It is a fairly decent little set and works well for Ham use. Many times when I have worked some of the group here I have used it as my main set because it is reliable. however I noticed that I could hear signals in the Weskit regen I could not hear at all in the DX394. At first I figured perhaps I was on a different freq so I dug out sig gen and did some more testing. I wasn't. Both were right on the same freq (7051.7) The extra stations I could and can hear on the regen were W7 and W8s and were easy to hear although not super strong. The Dx394 could not even pick them up or if it could just their presence but not copyable. And I have a lot more throttle in the regen left while the rf gain on the Dx394 was set full open. So I tried my other RXs. My HR10B which is no great shakes anyway but certainly a serviceable set as well as my Dx150 Realistic which isn't a bad set in its own right. As well as my No 19 Ws sets receiver which is not very selective but quite sensitive. Same result. There is no denying it . It is too obvious and too large a difference to ignore.
I have had similar esults with my Twinplex upstairs comparing it to my 9-59R trio or my TS830S's RX.
A simple triode regen with an audio amp added (preferably resistance coupled which avoids the howl) is a very practical rx even today for one who can run it.. The more we add to that design the less they seem to perform. And so it was with the first Flying Doctor RXs. He mus thave known that aswell because his rebuild took care of exactly that. Anyway should quit now. I get too into this fun stuff. I do just love this kind of radio though. Much of it is Lou's fault. He got me interested in the BK style rigs and now I can't stop building. (Thank you Lou!)

I don't know if anyone here has any interest but since I hang out here the most and we had talked about it I felt it was only fair to give this here. It is a very short, low res video of the wooden keyer I made this week in action that we were discussing earlier. It does work very well (for me anyway.) It automatically makes the "dah" on left swing. If you have ever worked me on CW you know I cannot send like this with a straight key. Not even close in fact.

Good video Don. However, I did not see it automatically sending dahs. I saw you manually entering the dahs you needed. Of course in that video you only needed two successive dahs for the Q, and you moved your hand to the left twice at the beginning of each ,Q. I would like to see it send multiple successive dahs, as I do not see how it can do that from the construction.. 73 - Mike

Well perhaps you misunderstood Mike.. It is not an electronic keyer. It is manual BUT: When you swing left it makes dahs when you swing right it makes dits. Certainly the operator picks the moment and direction but I do not form the dah. I only pick the moment. It makes the longer contact duration because of the left hand switch design and moment of intial contact. Ok let me put it another way. You CANNOT make a dit on a full left swing. Impossible. Whatever is sent on a left swing is always (approximately three times) longer contact duration then a right swing. No it doesn't go Dah dah dah dah by itself like a vibroplex does its dits. But a left hand swing always produces a longer contact duration then a right. I choose the contact connection moment of initial conduction by testing, moving the left hand extra contact along the arm manually till I was personally happy with the sound before I permanently fastened it to the main board. Perhaps some would like a longer dah (move extra contact closer to the pivot or dead end of the arm) or perhaps some would like it shorter (move extra left side contact closer to the grooved end or op end dowel.) On a left swing almost as soon as it is initiated the extra contactor on the smaller dowel on the left side of the arm completes the circuit and it stay completed as the swing left continues to the normal main contactor in the groove. That main contact serves more as a stop then a contact however it is required to keep it wired as well in case the arm or blade should bounce and a stutter be introduced. (An ounce of prevention beats a pound of cure) The left side contact is still there until the arm swings back on its natural springyness almost completley but not quite to zero or neutral position where the extra contact left circuit breaks open. So not only does it start early it finishes late. Adjustment of the extra contact is made so it breaks clean and doesn't accidentally trigger when the deck is bumped etc but it is as tight as possible clearance wise (approximately .024" I would say using my experience as an automotive machinist of some 45 years.)
On the right hand side there is no extra contact. Just the main one in the groove. So there is no conduction till it hits home. You could make a dah here if you wished I suppose by holding against the contact. For what reason I don't know. However you can not make a dit going left. it always is longer .
I know it may seem confusing. It is something I had thought about for years but never bothered with. After getting into the cootie thing and making one I couldn't resist trying it since it is so simple to add. I was surprised how well it worked. I hope that helps explain it at least some. It is probably an outgrowth of my work in rocker arm ratios and camshaft design which is an area I understand very well, involving ramp clearances, effective duration vrs advertised duration. Same sock factory, different area.

Since buying this old blister for this experiment I have struggled to gt it up and running. A couple of times I wished , well U know. First thing I found is one tube forced wrong in the socket breaking the locating key. I was able to coax the broken piece free and repair the tube (crazy glue). I also found a trashed cathode resistor in the PA. Next I discovered a couple of hundred volts vanished as the B plus flowed through the speaker magnetizing coil which also doubles as a filter choke. I bypassed it with a HD filter choe from my junk box. Now I had to come up with a transformer and perm magnet speaker. I had made such a device with clipleads but had lent it to another collector and hd to go find it and retrieve it. Several paper caps were warm and some dripping. I replaced all but two with orange drop spraques of not exact but acceptable values. Finally I traced the final fault to a .002 cap and although I didnt have one a .001 orange drop stood in just fine. At 3:04pm the old 1930s set barked to life. It is a pretty good working radio I think. Has a good Rf stage ahead of the main set so seems pretty decent. It cover broadcast of course but also 160M but stops right at 3.5 mcs. Next band starts at 5.6 mcs . However it covers 40M and I have already tested the adapter set in this set using its 6F6 tube in the Tx socket. I wanted to try a QSO with MCW but I think it would be frowned on. So I arranged for a friend to stop by tomorrow and operate my No 19 set into a old style dummy load on MCW and see of I can receive with the earphones plugged into my adapter and if I can return the signal. That is about as close as I can get to real life conditions of 1935 to 1945. I know our US friends are not allowed MCW in the HF bands. We may or may not be. I cannot tell for sure but I sure am not going to phone and asked. Never invite government trouble is my motto. I will have to be happy with the dummy load in a nearby room.
Anyway if that goes well I will have completed the project and tried everything I wished in some form.
donVe3LYX
Set is a Stromberg - Carlson Model 61 as would have been found in many homes around here in the late 1930s early 1940s. I also tried the set today in my brothers GE H-77 floor radio. Worked fine. It also has several SW bands.

14008. Antique Wireless Association Schedule of Current On-The-Air Events 2016 - 2017

From: Louis Vermond
Topic: 14008 Message: 14008

Antique Wireless Association Schedule of Current On-The-Air Events.... 2016 - 2017

This schedule lists our current events including the last event for 2016 and the first 3 for 2017 which makes more sense than listing them by year. Final details on each of these events (including rules and log sheets) will be available on the AWA website www.antiquewireless.org about one month before the event. For additional information contact Tim Walker, W1GIG@... Good luck and have fun!

2016

Event: AWA Bruce Kelley Memorial CW QSO Party

Dates: Sat. Dec. 10 @ 2300 GMT to Sun. Dec. 11 @ 2300 GMT

And Sat. Dec. 17 @ 2300 GMT to Sun. Dec. 18 @ 2300 GMT

Bands: 160, 80 and 40 Meters

Special Conditions: Contest is for those who design and build low power self excited oscillators (no crystals!) from the 1920’s. Open only to hams using transmitters meeting the requirements, both AWA members and visitors. Design must predate 1929 and use early tubes. Construction to conform to design using the earliest parts available. Receivers, old is better, but not required. High scorers should send in full details on equipment design and station photos. Logs are due four weeks after event

2017

Event: AWA Linc Cundall Memorial CW Contest

Dates: Wed. Jan. 11 @ 2300 GMT to Thu. Jan. 12 @ 2300 GMT

And Sat. Jan. 14 @ 2300 GMT to Sun. Jan 15 @ 2300 GMT

Bands: 160, 80 and 40 Meters.

Special Conditions: Contest designed to favor those using low power and equipment constructed before 1950. But, all are welcome, AWA members and visitors both. High scorers should send in full details on equipment and station photos. Get that WW II surplus on the air! Logs are due four weeks after contest.

Event: AWA Amplitude Modulation QSO Party

Date: Sat. Feb. 11 @ 2300 GMT to Sun. Feb. 12 2300 GMT

Bands: 160, 80, 40 and 20 Meters

Special Conditions: AM is required. All ages of equipment and all power levels. Extra credit for working one or more Flagship Stations, typically W2AN (AWA) and W1HRX (Millen’s

personal call). Please send us a log so we know who is out there. They are due four weeks after the event.

Event: AWA John Rollins Memorial DX Contest

Dates: Wed. Mar. 08 @ 2300 GMT to Thu. Mar. 09 @ 2300 GMT

And Sat. Mar. 11 @ 2300 GMT to Sun. Mar. 12 @ 2300 GMT

Bands: 40 and 20 Meters

Special Conditions: CW contest designed to favor those using equipment constructed before 1960 with straight keys. But, all are welcome, AWA members and visitors both. High scorers should send in full details on equipment and station photos. Logs are due four weeks after contest.

Not to split hairs, but I thought that the BK design requirement (however interpreted in practice) was to "predate 1930", not 1929. To me, the way this is worded implies *1928* designs or earlier. (Somewhere in my mind's eye I see Ross Hull holding the Wouff-Hong and shaking his head in disapproval.) I don't expect there are there are any changes to the rules, but a newbie like me might get confused. Lots of good things happened in 1929, including ever-popular '45 tubes.
I've never participated in a BK event, so this year I picked a year (1924) to design for, started reading period sources, and decided to go for it. It's been a blast thus far, and whatever small dent went in the wallet has been well worth the learning.

So when one wins what does one get. Honorable mention on the web site(done)? A frameable certificate or what? I was told by someone they had several plaques on the wall. Must have been a figure of speech. Did I miss something or simply misunderstood? Not that it is a big deal but I am curious.

If you are referring to the Bruce Kelley event, it's not a figure of speech Don. I can verify that whoever has the highest score gets a very nice plaque to hang on the wall. They are about 8 x 10-1/2 inches, dark hardwood with a nice brass plate on the front. I had a picture somewhere, but can't seem to locate it right now.

It says 116 days on my computer after I plugged in Dec. 10 and restarted the counter. We had originally assumed Dec. 3. Please be sure to refresh the page...

Oh Ok. The reason I asked was it has been quite awhile and I aint seen nothin nor even had an email. I know it was a lucky win perhaps for me but I would like something to hang on the wall since it is unlikely to ever happen again once the more experienced are back in the game. I am somewhat shy (I know you wouldn't have believed it but I am) I don't know how to deal with this. I would have thought if there was something, even a printable certificate I would have it by now or am I rushing things? I don't want to cause any trouble but can't help but wonder.

Don it does take some time for the plaques to show up. Last year I think they held them until after the convention to see how many they could hand out there (if the winners were there) before mailing them out. I got my plaque for the 2014 BK in mid September 2015 (10 months after the event). Not complaining, just commenting that it does take time. In other (non-AWA) contests it often takes 12 months as they mail them out just before the next running of a contest.

I finished this all just now. I plugged in the spy adapter set to the old Stromberg Carlson. Warmed up the No 19 WS on MCW and hooked it to my dummy load. The two sets are in different rooms. I tuned the Stromberg to the same freq as the crystal (before plugging it in) I put my video camera between the earphones and plugged them into the adapter set plug where it goes into the socket. It steals audio from pin 5 which is the Audio PA grid or the Audio driver plate (north of the coupling capacitor) and ground. It works quite well. I sent a signal and it was easily heard in the earphones so we know that works. Set tunes freq as normal and is actually very selective. Better then my No 19 is. Then changing nothing I put the No 19 on Rx (pullout the key plug a bit and switch to CW)
I sent a reply from the adapter set. I used German (Karl ?K... Ja Ich bin hier K) just to keep it all period correct. I had no real antenna hooked to it but just clipped it to a voltmeter lead to ease my conscience. Could be heard in the WS No 19 and I recorded it as well. The 6f6 in the Stromberg is a bit stubborn. I dont know if that is because it is tired. (only 78 years old.) or perhaps it isn't a wonderful PA tube. I don't know because I don't have a spare to compare however I popped in an average 6v6 I have and it worked fine. In fact it is now in the set as an audio tube and is noticeable stronger. Whether that is tube characteristics or wear factor I am not sure. Since voltage is the same (same radio, same socket)although the 6v6 can stand much more I suspect it is a semi bum 6f6 ube.
Anyway. It works. I am satisfied that it would certainly be possible to carry on operations, both send and receive, in this manner. However I wanted to actually do it and be absolutely sure it all works. Beyond this ?
I may drag it out for the Linc Cundall event or something.
Anyway, It has been for me an interesting and fun project.
donVe3LYx

---In AWAGroup@yahoogroups.com, <dulmagedon@...> wrote :

Since buying this old blister for this experiment I have struggled to gt it up and running. A couple of times I wished , well U know. First thing I found is one tube forced wrong in the socket breaking the locating key. I was able to coax the broken piece free and repair the tube (crazy glue). I also found a trashed cathode resistor in the PA. Next I discovered a couple of hundred volts vanished as the B plus flowed through the speaker magnetizing coil which also doubles as a filter choke. I bypassed it with a HD filter choe from my junk box. Now I had to come up with a transformer and perm magnet speaker. I had made such a device with clipleads but had lent it to another collector and hd to go find it and retrieve it. Several paper caps were warm and some dripping. I replaced all but two with orange drop spraques of not exact but acceptable values. Finally I traced the final fault to a .002 cap and although I didnt have one a .001 orange drop stood in just fine. At 3:04pm the old 1930s set barked to life. It is a pretty good working radio I think. Has a good Rf stage ahead of the main set so seems pretty decent. It cover broadcast of course but also 160M but stops right at 3.5 mcs. Next band starts at 5.6 mcs . However it covers 40M and I have already tested the adapter set in this set using its 6F6 tube in the Tx socket. I wanted to try a QSO with MCW but I think it would be frowned on. So I arranged for a friend to stop by tomorrow and operate my No 19 set into a old style dummy load on MCW and see of I can receive with the earphones plugged into my adapter and if I can return

the signal. That is about as close as I can get to real life conditions of 1935 to 1945. I know our US friends are not allowed MCW in the HF bands. We may or may not be. I cannot tell for sure but I sure am not going to phone and asked. Never invite government trouble is my motto. I will have to be happy with the dummy load in a nearby room.
Anyway if that goes well I will have completed the project and tried everything I wished in some form.
donVe3LYX
Set is a Stromberg - Carlson Model 61 as would have been found in many homes around here in the late 1930s early 1940s. I also tried the set today in my brothers GE H-77 floor radio. Worked fine. It also has several SW bands.

Hello Bob,
? ? ? ? ? ? ? ? I appreciate you getting back to me about your HT-9 and curls you have for it. I could be interested in one of the following.?

1) The HT-9 you have with all of the curls and tuning units you have for it.

2) The 160M coil specifically if it may be available along with the 80M coil if you would split them up. If not, just the 160M coil. ?Ditto on any tuning units you have for the aforementioned coils.

Not that it is important, but rather a matter of curiosity, is your HT-9 "black" (pre-war) or "gray" (1945/46 version)?

Please let me know what you are looking for get for the complete HT-9 "package" with it's curls, any tooning unicks, etc etc. and if available the 160M curl you may or may not have for it. As with anything else, My funds are somewhat limited due to both Jocelyn and I being retired now, BUT may be able to swing both as Jocelyn's Christmas present to me!?

I'd LOVE to do a visit and pickup of both the AR-88 AND the HT-9 if you still have both. They would make a great station together! Optionally, my SX-28 or 28A wouldn't mind doing rx duty next to your HT-9.?

BTW, do you have a knowledge of the speech amp sets the HT-6 has? I believe the early ones used a 6F5 and another low mu triode as the speech amp, and the later HT-6 used the triode section out of a 6SQ7 and another triode or dual triode. Any information you may have would be greatly appreciated so I can proceed with the HT-6 I have. ?;

Hello to Alice from Jocelyn and I and looking forward to hearing from you!

Joe NTree-IBX

I am still interested in Spy activity (as it relates to my adapter set experiments) just before the WW2 and so keep poking away at it in my spare time.
Just stumbled onto this from 1936 Marine Archives.
" At the present time, Picton is the main inland harbour for the Bay of Quinte area for the loading of water-borne cargoes for the markets of the world. Goods are brought to the local docks from an area of more than ffity miles. It is not uncommon to see ocean going vessels loaded at the Picton docks for overseas destinations.
[This document, author unknown, from a manuscript dated 1936. We have neither edited, nor corrected known errors]"
Timeline fits exactly. (1936 to 1939) What caught my eye was "Ocean Going Vessels"
The more I look the more interesting it becomes.

Belleville And Trenton both had several forms of Munitions manufacturing in full swing during the war. Picton or Port Milford are the harbours that would have been used. And there were and still are) four wartime military bases within 15 mile radius. 3 RCAF and One Canadian Army.

If there wasn't spy watching there should have been. I am beginning to think more and more my hunch may be correct.

I'm stumped on this, but that's probably because its a piece of spark or telegraph/telephone technology that I'm not familiar with. They have a heavy ceramic bases and three slabs of dark gray material sandwiched between the electrodes with very light spring tension--they just kinda sit in there loosely. The outer grey slabs are conductive, the larger inner one is not. It's labelled L.S. Brach Supply Co. There appear to be two separate units in parallel as it appears they were designed to do.
I'm looking to learn something new. Any hints?
Thanks,
Andy K0SM/2

Mark,
I think you provided the necessary hint. It's appears that it might be a carborundum lightning arrester. I've never hear of one, but I've never paid much attention to lightning arresters. It would explain why it was in a box that had some other crystal detector odds bits. It's probably intended to be a supply of detector material.
Thanks!

14033. New "1924" transmitter

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-08-22 01:25:27 UTC
From: aflowers@frontiernet.net
Topic: 14033 Message: 14033
Attachments: 2 described; binary payloads are missing from this source WARC

Here's a couple pictures of the transmitter that won the Matlack award this year, to which Mike was alluding. It's a reconstructed "1924" transmitter for the new 80m and 40m amateur bands that amateurs got that fall. I'd tried to make this as close to a 1924 as possible from here in 2016. It uses all parts that were available in late 1924 and constructed following period guidance in magazines or other sources of knowledge that were available then. For example, the plate-block and grid condensers were homebrew from mica, copper sheet, and salvaged bakelite according to an article in "Radio" from Feb 1924. The inductance is solid copper and wound and mounted according to instructions published in early 1925. The choke comes from a 1923 QST article and some suggestions in the old Radio Corp. apparatus catalog. For the manufactured components (meters, jack, variable condensers, binding posts) I found advertisements to verify availability in the fall of 1924. For example, Weston changed from "Co." to "Corp." in early 1925, and at some point this was reflected on the meters themselves. I had to use the "Co." variety for this project....

The circuit is a Hartley with parallel UV-202s and center tap keying. The "oversize" RCA rheostat--which they advertised for use with UV203's and UV204's has enough range to allow operation of parallel UV202's with both a period 10V and a 8V storage battery, or an AC filament transformer depending on what kind of power you had available back then. (You can jumper the center tap to one of the A terminals if you are using a DC source for the filament and don't want a resistive divider). It would be versatile, particularly if your AC was not reliable and you wanted to be. Remember, two 202's will draw in the ballpark of 4.5A of filament current, which is getting close to the 6A a single UV203 would draw. RCA wanted you to use one PR-535 on each tube, which was a couple dollars cheaper in 1922, but that didn't allow you to use constant filament voltage with a single meter as you were supposed to do in 1924!

I worked Lou with it, although I think I had 71A's in the sockets at the time. He also saw it putting out several watts at his house with a pair of 10's. It sounds fabulous on 80m, but I haven't been able to get a good tone out of in on 7MHz. Of course, tone quality standards had to have been pretty low in 1924. My HV supply is having some issues right now and I haven't been able to see just how much it will put out with the 202's at rated plate voltage, but once I get that straightened out I'll let people know and I'll put it back on the air some evening. It should loaf along at the BK power limits this December.

Andy K0SM/2

14036. News from the spyfront: 2x Type 10 transmitter

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-08-22 08:02:42 UTC
From: thomas.hoeppe@...
Topic: 14036 Message: 14036
Attachments: 1 described; binary payloads are missing from this source WARC

Hello!

Don opened the spy topic with his interesting adapter transmitter, and his reports to use it in combination with the right domestic radio receiver. As I told you when I introduced myself here on the reflector, building spyset replicas is one of the main parts of the "vintage hobby" in my case. I built some units from the SOE, some German "Abwehr" (WW2 military secret service of the Germans) and others, Recently I finished the CMS receiver, and next will be the CMS transmitter.
I was always interesting to get more technical information about the radio sets used by the "Red Orchestra". This was the name the German "Abwehr" gave the communist spy networks in Europe during WW2. There were several subgroups active. A lot of books and movies are available, but the technical background remains a miracle. It is reported that they often built their radiosets in small local workshops. These days I stepped over a book where there was a schematic printed in. It is the transmitter of Dr. Sorge, a communist spy that worked against Hitler-Germany in Japan. He collected war-imprtant information and sent it to Moscow. He was caught by the Japanese secret police, who made drawings from the local setup of the transmitter and from the schematic. The drawings are of very bad resolution. Some parts are inscriped in Japanese letters, and I can't read that. I tried to redraw the schematic. If there are lines crossing themselves, there are either "half-loops" to show there is no connection, or dots to say there is connection. One crossing is unclear. There was no loop and no dot. I marked that point in red. May be someone has an idea!
The schematic is amazing. It uses 2x Type 10 (UX-210) tubes. They are rare in Europe, but common in North America. Some of you use them in the Hartleys or TPTG transmitters. In that schematic they use "self rectification". You can't expect a T9 tone, hi. May be this transmitter design is interesting for some of you in comparison of your vintage type 10 designs. Any ideas about that unclear point are wellcome!

73s de Tom, DJ5RE

I have a detailed article by the famous Ross Hull on the subject of self rectification and post 1929 operation,
I will send you the schematic he has for how to build it and use it.
His final statement is surprising.
"..the self rectified transmitter is an entirely practical proposition so long as the amateur is willing to build it correctly and maintain it in precise adjustment. " He said it was his conclusion after weeks of "dabbling with the design"
I have thought of building a 01A version just to see however I may already have too many sets.
The one in Hulls article used ux-852 tubes. He goes into great detail on how to avoid the pitfalls of the design.
I will send you a pic of the schematic later today when I get enough natural light and perhaps you can use it to compare.

Hello Don,

yes, I am very interested to read that article. I think Hull was the man of that time who proved that some designs are working much better then the common opinion said, when you take respect of some construction details. All those old schematics look simple on the first view, but the ups and downs are included in the details. Making this details right is a question of practical experiences. Knowing where you find the □knobs to turn□ in those designs is the tricky part of the game. The □old ones□ knew most of them. We have to find them again. But it□s an exciting affair, isn□t ?

Most fun I have had in the hobby. All Lou's fault BTW.
I sent you the pic , the schematic and the parts list. I have some work to do for the XYL this morning (painting a room) then I will start scanning in a page at a time for you.
As for further adventures of the Adapter Set I had mentioned the 6f6 from the Stromberg Carlson was suspect SO I took the adapter set and plugged it into my bench supply (all my bench supplies are wired to the 7AC /7S standard tube base pinout so any set here can plug into any supply without disaster. The Adapter set also happens to use that so it works out nicely) . It is a bit better then the host radio would supply so I figured it was a good place to check it out with the 6f6 tube in the socket. result was identical. Tube works for about a minute or so then gets stubborn so It is safe to say it is a bummer. I am using a 6v6 in place of it but may order a new 6f6 just to keep everything honest. However that said it did work with the 6f6 in both the host set and the bench PSU so that part is still valid.
Taking up a notch I am wondering if any early hams would have added a BFO type function to an old home radio and used it as a station RX along with the ARRL version of the Adapter style TX. It seems to me for a poor boy set up (or cheapskate) it would have been very practical if anyone did. The Stromberg Carlson is a much better receiver then my Heath HR10B or my No 19's rx section or my BC454 . Very selective and very sensitive. So if one did make it ok for CW reception they would have a pretty decent station for the time.
So much so that I have decided to keep an eye open for another repairable chassis. I don't want to mess with this one as I want it honest to the spy adapter set application.

Hello again Don!

The pictures of the Hull article arrived thanks!

I have also been thinking if normal AM receivers were modified with BFO. There is an interesting story. When I started with my Hartley, I had several contacts with Carlo, IZ4KBS. We made several test QSOs. He transmitted with his Hartley, and I made digital records of his transmission and sent them to him via Email. He told me about an Italien arctic expedition in the 20□ies. The transmitter was called □Ondina□. They used a vibrator style PSU with nearly no filtering. May be they wanted to keep the weight low, or the early electrolytic capacitors did not work in the cold. They got troubles and needed help, so they started transmitting. A russian BC listener received their signal and could get the morse code with his AM receiver, as it was modulated due to the lack of filtering. He called for help and they were rescued. Carlo built a vibrator PSU for his Hartley, with switchable filtering. He wanted to □simulate□ the sigs of this transmitter. It works! The hum in the signal makes the sigs readable in AM mode on the RX side! It is not perfect, but good enough for CW.

Less is more! It saved lifes in that case!

Tom

It was interesting to me that the new 1924 amateur regulations in the US did not allow interrupted CW (chopper or buzzer modulation) anywhere except a small portion of the (old) 200m band. I can understand legislating out spark, but ICW shouldn't be quite the wideband source that spark was. I guess it was assumed that C.W. and the use of a BFO or regenerative receiver pushed into oscillation was the future. Claude Shannon was only 8 years old in 1924, but you can see there was an interest in using minimum necessary bandwidth to communicate information given the growing need for sharing spectrum among various services.
That said, lots of people ran some form of AC on the plate in the 20's and probably could be copied just fine without a BFO. I suppose a 500 cy. generator would sound pretty neat on a detector, but it would also be 1 kc wide before any IMD products!

You are probably correct in your assumption by 1924. However, tube type CW transmitters were available to hams way before ’24, and a lot of times they used a chopper in the receiver end. If the receiver was a crystal set, or just a detector and amp, non regen., the CW could not be copied without a chopper in the receiver. BTW, congrats on the Matlack award. It is well deserved. A little birdie told me about it, HI. 73 – Mike

I did not get the impression that Ross's self rectified design had a "bad" signal.
My impression was it works similar to a push pull deal. Anyway time will tell.
donVe3LYX
I use vib supplies here sometimes. Stolen from 1950s car radios. They work pretty good.
The big trouble is with direct heated tubes it doesnt work too well because the old suppplies have the heater and the B neg already grounded. however one could key the centre tap i suppose . I am not big on keying B plus.myself. With 1930s tubes , indirectly heated it works wonderful.

With the properly designed and operated self-rectified designs you get the effect of a full-wave rectified, unfiltered HV supply: a carrier 100% modulated with a 120Hz sine wave, i.e., A2 telegraphy. By definition, not "T9."

Hello Don!

I also don☐t like keying B+. I even don☐t like magnetic headphones for the receivers in the HV+ line of the final tube. I always add a choke and a relieable capacitor as DC blocker. I have some replicas where the originals had DC on the phones, but I changed that. Security is one thing, the other is I use a LS3 speaker very often. This one has one side on ground (1/4☐ connector) at the input side.

I also tested a vibrator PSU for the paraset. The voltage was fine, but the drop in voltage during TX was very high. I looked at the output without filtering. The ☐on☐ segments on the screen were very short, with long ☐off☐ phases between. No wonder thze voltage was not stable. May be the vibrator was already damaged.

Tom

Hi Tom –

That point that you have in red should obviously not be connected. If it was, there would be a 2500 pf to ground from the grids of the 10's, or at essentially at DC ground eliminating the feedback path. I am not sure of the reason for those caps other than to keep the variable from having the full DC on them. What do you mean by small workshops? Were they put together in Japan or in Russia? The Japanese copied a lot of our tubes directly and even gave them the same numbers. So, it is possible that 10s would be available in Japan. A lot of the Japanese tubes used in WWII can be directly substituted by US tubes. During the war, the Russians were our buddies, and also used some similar tubes as we did. 73 – Mike

BTW, I sent the same email over 4 hours ago and it never made it for some reason. So, two of them may show up. 73 – Mike

Sorry Mike, I forgot to answer your mail completely!

The ☐Red Orchestra☐ had specialists, often owner of radio shops who also did repairs for the customers. When thise people had spare tubes or measuring equipment, it was not suspicious. This people were able to build the transmitters themselves. One transmitter in Switzerland was built inside a typing machine. In the case ☐Dr. Sorge☐ they even built the morse key themselves. In Berlin, the group around Harro Schulze-Boysen had an accident with their radios. One fell down, and one, built for AC mains, was hooked up to DC mains and was damaged heavily. Again the group had a specialist who made the repair.

Hello Mike!

Thanks for your comments about that unclear point. I only got one mail from you so far. Today I got another schematic from a friend. It is also with japanese letters. When you look at the □critical point□ of this schematic, you find it in the lower left corner, you see that the person who drew this one had again problems with this detail. He made a □jump-over loop□ but added a □dot□ as well. Of course the dot makes no sense, as the key would be shortcut if the dot would be right.

The whole setup seemed to be pretty ugly. Look at the picture .sorry for the very bad resolution. The difference of both schematics is exactly on that point!

The basic premise of Ross Hull's test were that he was able easily to get a single tube self rectified quickly down to an occupied band width of 240 cycles. mostly by using high Q and careful maehacnical construction. He said the problem with two tubes is they dont run always at the same frequency if the circuit is not physically identical for each. At the end he could get it down to 540 cycles 9these include any sidebands BTW) and suggested that might not be the absolute bottom available . (Things like separate heater rheos etc come to mind) He also mentioned the common use of UX210 tubes although hehandicapped himself a bit by using 852s I believe it was. And he gave instructions for tank circuits for 80M (7 turns of 3/8 copper tubing with an outside diameter of 3 3/4 inches, 40 meters . 6 turns of 3/8 copper tubing wth an outside dia of 3 inches and (and i hope you re all sitting down!) 20 M . 3 turns of 3/8 copper tubing with an outside dia of 2 1/2 inches.
I suppose we could discuss the pros and cons all day but IMO Ross Hull was no ones fool so i tend to give lot of credit to his words. Many of us use his designs nd advice even today on our vintage builds.
One could crtainly build it, try it on AC for nostalgias sake once or twicw then feed it well filtered Dc ever after. I am sure it would be fine as some and better then most anyway. It was for me an article well worth reading wether i ever build one or not.
Lou sent me a different design but in a similar vein many years ago. I think i still have it saved on this notebook.

My brother Dan, mr retired Bell Tech, (Joe C knows Dan from ST-WR rx research) stopped by to see the pic of the "what is it thing." You folks guessed right. He says it is a lightning protector and although not the brand Bell Canada used is very similar. The carbons on the end are covering a short carbon in the middle of that stone like chunk and dont quite touch leaving a small gap. When hit by lightning the gap is easily bridged and the circuit stays protected however it now needs as they say new carbons. He said the base should be varnished wood and normally if you turn it over there should be a dated stamped in the wood. He said it is very old. He has one of ours at home and may bring it down and show me. He also said Hydro (How we call our Electrical supplier here) also used telephone systems based on carrier transmitter designs for their own company use and they protected everything with similar devices.

A bandwidth of 240Hz is what you'd get from a carrier modulated with a pure 120Hz tone with no harmonics. But with a single tube you'd get a 60Hz tone, so maybe the 2nd (audio) harmonic was significant.

Jim
Because the Str/Ca Model 61 receiver works so well I am going to try the pseudo BFO. I think I can do it without opening the set all from the 6sk7 IF amp. I will use a safety sandwich to insure I don't accidentally ground anything but I am going to give it a try . Probably this weekend. I have been thinking about it ever since I got this radio running and had hesitated because I didn't want to modify it in anyway. Then i realized I might be able to to it all from above with two thin insulated hook up wires, a 470ohm resistor and a switch. If so then it is something that would have been possible to do to someones home set without their knowledge and that is my goal. Might I take a moment here and thank you for the tip.
The XYL gave the green light for a late 1930s parlour downstairs. I have chairs , a sewing machine (treadle) the two old wooden radios . All I need now is a spinning disc TV!
If it all works out I plan some relaxing ops using the adapter set and the Stromberg Carlson.model 61. BTW I am using a 7050 crystal. That is not good since I don't like excluding anyone from the possibility of a QSO so I would like to move up. i think anything above 7110kcs is better but where? I have before me a 712o something, (cant read it) a 7140 , a 7115 and a 7190. I am thinking the 7115 and the 712o something but dont really know where to go. back in the day here when on the first license with it s restictions I kept all CW under 7100 on 40M.
But that was more tradition then rule.

7115 turned out to be a lightly stamped 7145.
So I am good on 7140kcs 7145kcs and the old 7050kcs. I can wiggle this set off that a bit to avoid QRMing. Is that too high or OK? What is normal? Currently tuned up on 7140kcs.
712o is a dud (so far)

Don,

The CW Classic Exchange is coming upon Sunday, 9/11 and Tuesday, 9/13. Our nominal frequency on 40 is 7045, but you should get a lot of action from your 7050 crystal. Do a Google search on Classic Exchange for more information.

Ok Jim,
BTW Today i went at the Str Carl 61. It doesnt have 6sk7 if it has a 6k7 (6sk7 was my brothers H-77 CGE set)
So on the 6k7 the grid wire is external anyway. I pulled the tube. Took a length of hook up wire and stripped about 1 1/4 inches. I wound it around the plate pin (pin 8) and then put the covered end out the side and up to the grid wire, winding it around 5 times just to see if it works . It does. Sounds very much like a audio feedback whistle like when a mic is postitioned wrong in relation to the speaker which is ok by me but it is certainly functional. The band is kinda dead right now however I will try it later tonight when there is more activity. I havent dealt with the AVC yet as this set has an unusual set up I dont quite understand yet so I am trying to figure out. I dont want to make any internal changes to the set as that defeats the purpose am using it for.
I have to go to Altona on the 11th but may get home in time to play anyway. The 13th should be no problem. I would be happy to try. I have to find some more 40M rocks. I dont totally understand the USA freq assignments but I believe some can't go below 7100 or is that only on phone?
Anyway thanks again for the tip on the IF feedback hetrodyne. Sure is fun. A young ham could have had a very good station unknown to the family as could a boarding spy. It is astounding how easy it is and how well it works. This old set with its Rf stage and all is very selective. Better by far then my HR10B heathkit for instance just to mention one. I am surprised an old consumer set would be so well built.

Thank you for the welcome. You can check out my QRZ page for some of my history. I am in the process of moving and during cleaning out the garage I found the National AGS including a power supply that I have moved and stored for 45 years. In the 50s I remember listening to it with my dad while he practiced receiving Morse code so he could get his license. When I get moved am hoping to see if I can get it operating again. Will need some advice on that process.

Hi Dan -

I looked on your QRZ page. The key you have there is an SE-68. There is also an SE-68A where the lever is smooth and not ribbed. Looks like yours may be missing the name plate, and if you look on one side you will probably notice the holes for the little nails that held it in place. Yours is also missing the legs. All of these had legs that were about 3 to 4 inches long so the key could be mounted to the operating desk with the contacts being the legs. Most hams cut off the legs so it would be easier to use and move around. You are right, the key is from WWI and was used with spark. It is a relatively scarce key and even in that condition it is worth about $300 to $400. The SE-68A is much more common.

Back about 40 years ago I had the opportunity to pick up an AGS for almost nothing an decided against it, which I regret.

About 5% of my junk can be seen here:

http://w2dtc.com/2007-0625-n4fs-page.htm

Best wishes with the move. 73 - Mike

Don, you shouldn't be hearing a whistle or any other tone, unless you
are receiving a carrier. Perhaps you have too much feedback (try fewer
turns in your "gimmick" capacitor on the 6K7 grid lead).

I just looked at the schematic for your radio (Riders vol 7;
Stromberg-Carlson Page 7-1), and to my surprise there is no AVC applied
to the IF amplifier stage. So you needn't worry about disabling the AVC.
AVC is only active in the RF and mixer in this radio.

Ok Jim,
BTW Today i went at the Str Carl 61. It doesnt have 6sk7 if it has a 6k7 (6sk7 was my brothers H-77 CGE set)
So on the 6k7 the grid wire is external anyway. I pulled the tube. Took a length of hook up wire and stripped about 1 1/4 inches. I wound it around the plate pin (pin 8) and then put the covered end out the side and up to the grid wire, winding it around 5 times just to see if it works . It does. Sounds very much like a audio feedback whistle like when a mic is postitioned wrong in relation to the speaker which is ok by me but it is certainly functional. The band is kinda dead right now however I will try it later tonight when there is more activity. I havent dealt with the AVC yet as this set has an unusual set up I dont quite understand yet so I am trying to figure out. I dont want to make any internal changes to the set as that defeats the purpose am using it for.
I have to go to Altona on the 11th but may get home in time to play anyway. The 13th should be no problem. I would be happy to try. I have to find some more 40M rocks. I dont totally understand the USA freq assignments but I believe some can't go below 7100 or is that only on phone?
Anyway thanks again for the tip on the IF feedback hetrodyne. Sure is fun. A young ham could have had a very good station unknown to the family as could a boarding spy. It is astounding how easy it is and how well it works. This old set with its Rf stage and all is

very selective. Better by far then my HR10B heathkit for instance just to mention one. I am surprised an old consumer set would be so well built.

I should have been more specific. I am referring to the note of the Pseudo BFO when reciveing a signal as in A CQ from my Adatper set or a signal from my GDO. No whistle when no signal. Sorry i wasn't clearer. Thanks for checking the scheamtic. I knew something in the AVC diagram. Couldnt find the 2m resistor which i thought should be there in plain site. It was different but then superhets ?I am a regen guy ;>) AVC there is done by whincing when your ears hurt.
So re 40M ops I will try again can everyone here legally operate CW on 7025 to 7120?
I want to get thi cleared up before I order new rocks

Yes, I did misunderstand and thought you were hearing that whistle tone all the time. Sounds like you have it working OK then. Yes, most US hams can operate the frequencies you mentioned. If they have an extra, like most of us do on here, then we can go down to 7 MHz. 73 – Mike

Mike,

You are correct, the SE-68 with modification makes a very solid key that I still use. The legs had been removed and the bottom has been machined out to run the connections. The thumb nuts were also added. The name plate is missing as you observed. The local ham that collects Morse code keys tells me by the construction that it most likely was manufactured here in the Seattle area. There were small differences with these keys depending on the location for where they were made.

The key and the AGS were stored in our basement for my uncle when I was very young. He worked for the FAA in communications which is how he most likely acquired it. I have found a schematic for it but not much more. I am curious as to how well the AGS performed as a receiver to know what to expect for performance if I put the effort into getting it working.

Hi Dan -

I looked on your QRZ page. The key you have there is an SE-68. There is also an SE-68A where the lever is smooth and not ribbed. Looks like yours may be missing the name plate, and if you look on one side you will probably notice the holes for the little nails that held it in place. Yours is also missing the legs. All of these had legs that were about 3 to 4 inches long so the key could be mounted to the operating desk with the contacts being the legs. Most hams cut off the legs so it would be easier to use and move around. You are right, the key is from WWI and was used with spark. It is a relatively scarce key and even in that condition it is worth about $300 to $400. The SE-68A is much more common.

Back about 40 years ago I had the opportunity to pick up an AGS for almost nothing an decided against it, which I regret.

About 5% of my junk can be seen here:

From: N3IBX
Topic: 14083 Message: 14083

?Hello Dan,
? ? ? ? ? ? ? ? ?My name is Joe Cro, N3IBX and could possibly help you with your "AGS". If you would like to contact me directly my email address is n3ibx@....

? I've been following your thread and from what I can gather you've had your AGS in storage for 45 years or so. That's a long time but not impossible to get it working again. I've tackled some sets that haven't seen electricity in 75-80 years or so and was able to bring them back to life with some TLC.?

Please contact me and let me know the particulars about what you know about it ie: was it working when put in storage, did it work but had problems, what power supply is in it, or did it use etc. If all original it probably has the hard to find "Mershon" early electrolytics in the power supply.?

I noticed from your picture you have a full set of coils for it or nearly so. As you know it uses three per band to cover a certain frequency range.?

Most AGS sets were used by various airports at the time but some wound up in the hands of some well healed Hams who could afford the very best. They are very sensitive and relatively stable sets, and have enough BFO injection to even copy ssb without any difficulty. They are relatively simple to operate which was one of the reasons why they were used by airports at the time. They weren't overly complicated to operate. Just install your coilset, interpolate from your frequency chart and there you were!

Let me know some of the particulars and we'll take things from there. I'd love to get a note from you telling me you got it working again. With a little help and TLC perhaps we could make that happen!

Very best regards and hope to hear from you.

Joe Cro N3IBX

Well, it's a superhet with 1 RF stage and 2 IF stages, and no provision for variable selectivity. So, I would say to expect the performance to be similar to the Hallicrafters, S-20R, S-40, National NC-100 (or NC-101 with bandspread coils), and countless other receivers, but probably with better mechanical and thermal stability than some of these. It would be fine for AM operation but broad for CW unless you're good at letting your brain be the filter. For it's time it was a Cadillac, though, and if it were mine it would be operational and frequently used in a prominent place in the shack.

73,
-Larry/NE1S

Don,

The 40 meter CW band in the US is from 7000 to 7125. Only Extra Class licensees can operate below 7025. CW is also permitted all the way up to 7300, but the phone band starts at 7125.

Thanks, I have had a time trying to sort this out. Sometimes when trying to set a sked I got a "I can't go there" and I became confused. I guess I got it backwards at first. I think i finally understand. Basically only Extras can sneak up to the lower band edge so to speak. Our tickets have changed over the years as well. I don't know the current ones, Just mine.
BTw there was a lot if activity around 7050kcs about a half hour ago. I was downstairs and turned on the old 1935-36 Stromberg Carlson with your suggested mod to it. It was wierd to here beeping coming out of this 81 year old radio. I have rebuilt the mod a few times with it a bit better each time. I think I can still improve it a bit yet. Tricky getting enough but not too much. However it does work and on this particular radio can all be done from up top. I installed a switch so I can switch it in and out. Thanks again.

From: JAMES HANLON
Topic: 13958 Message: 14092

Don,

I have not looked at the schematic for your set, but even if the IF stage is not on the AVC line, the set should work better if you arrange to ground the AVC line (or attach it to ground through a small resistor ala the S-38A etc.) when you have the IF stage oscillating for CW reception. Here's why. When the IF stage oscillates it puts a strong signal into the detector, just as a very powerful carrier in an AM broadcast station would. The AVC detector rectifies that signal and applies it to the AVC line, thus cutting the gain of the stages controlled by the AVC bias voltage way back. Unless you short the AVC line to ground, that bias voltage will greatly reduce the gain and sensitivity of your receiver on CW. If you do short the AVC line to ground, the RF stage, mixer, and IF stage will operate at full gain, and you can then adjust the overall volume with the audio volume control. You may find that more powerful CW signals tend to go into saturation with this much gain, in which case you may want to switch the AVC back on to reduce the gain in the "front end" of your set.

By the way, even receivers with a separate BFO as opposed to just an oscillating IF stage also turn the AVC off by shorting the line to ground on CW. The usual way to operate these sets is to turn the audio gain way up and adjust the overall volume with an "RF Gain" control which varies the gain of the RF and IF stages and sometimes also the mixer. You probably don't want to install an RF Gain control in your set, but if you did you could do it by putting a variable pot - about 20K ohms should do the trick - in between the cathode of the tube(s) to be controlled and ground. The cathodes should probably be bypassed to ground with something like an 0.01 mfd capacitor. The mixer is usually not included in this kind of RF gain control because varying the gain of this tube is likely to pull the local oscillator frequency, especially if the tube is a combination local oscillator and mixer like a 6K8 or a 6SA7.

I hope this makes some sense. If not please let me know and I will do a better job of explaining. A copy of your schematic would also help.

73,

Jim, W8KGI

Thanks Jim, I have been thinking about this myself. I can hear the AVC interfering with "comfortable operation " if you will and wondering how to deal with it. Not that it isn't usable I expected a rather straight forward approach but when I looked at the schematic it wasn't a traditional AVC. Not that I am an expert AVC person being a very strong believer in the wonderful performance of the Regens but I want this set up to be period correct. As would of and could have been done to Grandpas Radio when everyone was asleep. So anything internal for this particular radio is off the list however anything that can be accessed from above is Ok by me.

I referred earlier to a fellow who lived near my family up to his murder in 1939. The more I dig and after reading the book Tom recommended I am more certain then ever that is why he was here. There are a lot of reasons for that but that is anther whole story. My dad passed away this spring and he was one of this fellows friends.

I wish i knew what I know now last year or so as I would like to ask Dad some questions. You see my Dad graduated High School at about 14 years of age. He took whatever work was available then and invested in a Radio College of Canada correspondence course as radio was always a big interest in his life. So even before the war started here (1939) he was already educated to a reasonable level on the subject.

I want to ask him, "Did you ever help Wilhelm string up an antenna for a radio" Did he ever ask you about old earphones. Did he have a radio when he got his own place and if so what. However I am a day late and a dollar short as the old guys used to say. There is a lot more as I said to this story that I haven't yet shared.

Anyway, I want to keep this radio as it would have been but I will send you my schematic. I have it saved somewhere on this notebook. It uses a 6h6 det and AVC. It was the 6h6 being used as a automatic driver control in the No 19 WS set I defeated to be bring power up to almost X3 on the No 19 giving better abilty for mild DX and the circuit while not identical certainly has some similarities.

And I appreciate your input into this project.

I accidentally bumped into a fellow in Ottawa on the web (Thursday)who has been authorized to put in a 1500 sq ft clandestine radio display at the Trenton Air Base Aircraft Museum. I live 12 mi from that Museum and my Mom Flt Sgt Doris R Daniells aka "Flight Danny" was stationed there for a time during WW2. A few years later she met Dad and the rest is history as they say. So Trenton has more then just a passing interest. This whole spy radio WW2 thing has exploded it seems. Where it will lead I don't know yet. Meanwhile aside from the history I am having a ball running the stuff! Life at the moment is very good!

(and painting is done so XYL is happy)

In the dim late night with only a old single bulb pigtail hanging overhead the spy station sits totally operational a-top the old 1935 Stromberg Carlson floor radio. The Stromberg Carlson is also tuned to 7051 kcs on SW band 2 and a discarded single operator's earphone from the local Prince Edward County Sprague Telephone Exchange (Mountain View, Ontario) sits plugged into the spare jack on the Adapters plug receiving audio driver tube audio. An old Memmee Key set up found by a neighbour in an old house nearby sits hooked up and working as is the Adapter TX with the Stromberg Carslons audio PA tube plugged in and doing a fine job. The 7050 crystal is plugged in and the circuit has been pulled up almost to 7051kcs by the Adapter Set's tank tuning. The glow from the old Stromberg Carlson dial takes me back to my days before TV was popular and we stared at the glowing dial for entertainment as we listened. A time machine if I ever saw one!

I went down with the XYL to the south end of "The County" Stopped in Cherry Valley and took a photo of Willy's grave stone. I was told my Grandparents bought it with the help of a few neighbours so he would have a decent burial. Then we went down to Port Milford South of where he lived. In the 1930s the ship used to come right up in the Port Milford Harbour. There is nothing there now however shipping traffic runs by out on lake Ontario which can be seen in this photo. I took a chance their might be something there. I could see a white spot distinctly on the horizon and so got the field glasses from the XYL. It was a tall ship. There are a few on the lake this summer. One even from Sweden.(If it is so it will be berthed tonight probably at Kingston or Gananoque. (check boatnerd.com) It was headed east towards Kingston which is where Lake Ontario becomes the St Lawrence River and eventually empties into the Atlantic. I was moving quite fast as in the time we were stopped it covered the entire space between the two tall trees. Too bad it doesnt show up in the photo. Anyway of that is what he was doing this is where he would be standing to do it. They used to operate a Life Saving team from the farm just in front of me here rescuing vessels in distress off the lake. This is also where all the booze left headed for New York State during prohibition. (Booze, Boats and Billions by Bill Hunt.) Anyway it will take a while to sort this all through if it is even possible. I was unable to find the house and barn where he was murdered so I suspect it has been torn down and a new house put up. Or I could just be getting oldand have forgotten. Anyway that is about it. The Sp set is installed on the Stromberg Carlson and running. Hopefully we will get some good conditions soon and I can do a couple of complete QSOs on it. (Send and Receive.) thanks everyone who pitched in with suggestions and such during the project.

Don,

OK, I've got the Model 61 Schematic, and you are quite correct about the AVC being applied to the RF stage and to the Converter (OSC.-MOD) stage but not to the IF stage. I understand your not wanting to make any modifications under the chassis, but I can see no way of disabling the AVC by going at it from one of the tube pins, which would be an above-the-chassis modification ala what you have done to make the IF stage oscillate. To disable the AVC line, ala what Hallicrafters does in the S-38a, you would need to connect a 470 ohm resistor between the junction of R15, R5, and C14 (if I can read the part numbers correctly with my tired old eyes and a rather fuzzy schematic). That would amount just to connecting the 470 ohm resistor across the AVC capacitor (.02 mfd) and ground. If you used a spdt switch as the S-38a does, you could accomplish setting the IF stage into oscillation and disabling the AVC line at the same time as the S-38a does, but you would have to make that one, underchassis connection. I think it would be worth it to give it a try and see how it affects the operation of the radio on CW. You wouldn't even have to make a solder connection, just a simple clip lead would do the trick. Someone working on granddad's radio back in 1935 might have gone that far.

Jim

14098. Salvaging inductance switch contacts (taps)

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-08-30 02:03:58 UTC
From: aflowers@frontiernet.net
Topic: 14098 Message: 14098

I salvaged several switch contacts from a piece of junk this evening and came up with a method that worked pretty well. There may be better ways to do this, but I'm sharing what worked for me in case anyone desires to do the same.

I had an old broken panel with some binding posts and inductance switch taps. It look like it used to be an old crystal radio more or less following the 1922 NBS pamphlet (only short a few taps). The wooden box was a wreck and there were no other parts with it. I wanted to get the switch contacts out because they might be useful in another project. Each contact had 6-32 threads and had been fastened to the panel with single nut. The owner had then soldered wires to the tips, which of course mucked up the threads makes uscrewing the nut impossible. The panel was wood--I didn't need to save it but I didn't want to start a fire either. So no torches. The space was tight, and getting in there with a dremmel tool to cut off the ends wasn't going to work, and it wasn't going to leave me with much left to reuse anyway. I wanted to get them out in one piece if possible.

First I soaked up or knocked off some solder with some wick. This stuff was gooey and dirty, so I had limited success with this, but it was a start. I did *not* use flux because I didn't want it running down the threads.

I found that I could grab the contacts from the front with a drill chuck on a variable speed drill, or if not enough room just some needlenose pliers. While holding the drill in one hand I placed a 100w gun on the tip of the bolt on the inside of the panel with the other hand and let it get nice and hot. By pulling on the contact from the front while rotating the drill slowly the friction held the nut against the panel and allowed it to unscrew. The nut pushes most of the solder off the end or onto a blob on the nut itself, and when finished you have a lightly tinned switch contact that you can put a new nut on without too much friction in most cases. The lack of flux is probably helpful in pushing it out of the threads.

ok Jim, I have a SPDT switch mounted on a bracket attached to an unused hole in the chassis. I am going to draw in the mod in pencil and sleep on it. I guess once I have logged a legit QSO then I would be free (in my own mind) to mod it anyway. I am hoping band conditions improve in the next few weeks and head toward non summer conditions. And I understand if it makes no sense to others that I feel the need to do a QSO on an unmodified grandpas set. I wish I had another. One thing I discovered is spotting the rx onto the tx is very easy. It can be put bang on everytime. So I need a 470 ohm resistor from the AVC .02 cap to ground in some fashion. Thanks once again. If I had another chassis since it is a very selective radio. A few minor mods along with your mods and it would be a real practical shack set.

Hello Andy, I've often wondered how to save those "buttons" of sorts that you salvaged from your inductance. They are few and far between and most useful when embarking on a new project or doing a restoration. Many thanks for sharing your method of removing them. Your 100W iron really came in handy for getting them hot enough so the solder would flow from them!

Best regards,

In the QST article 'A Flexible Transmitter' (Mar '27 QST, pg. 33) rf chokes are called for in the Grid and Plate circuits. The only ref. to construction/ value is this: 'Both grid and plate circuits are isolated at rf by the usual (?)* rf chokes which are in this case, small honey-comb units which are effective when wound with small wire.' Anyone have any idea on the value and/or another construction method that would give the same result as the honey-comb construction...turns, wire size, dia, etc. Do ya think a jumble wound coil of a few hundred turns would work? I have no idea ...just guessing. And the same construction questions re. the honey-comb version. Tnx for any ideas....73 de Bill K4JYS

Back before I bumped into the gang here I always had a hangerin for low tube count radio. I had built a BE and that is how I met most of you the night I was challenged to fire it up on the air. Then Lou got me interested in the 29 and earlier stuff. However I had even back then started a build of one for that style of rig. I had made the coil from a web site diagram and I printed out the build. This week while rooting through my junk box drawers for some crystals (doing custom replica adapter set for a fellow from the original German text and circuit he provided)I came across it. All neatly wound and varnished. IT seemed like such daunting project way back then. But now I don't understand why. Anyway with less then a hundred days to BK I think I will finally build it perhaps with my No 10 tube for the event. I am going through some of my "less then stellar" experiments (I know I am the only one with such things) and dismantling them to resurrect the parts in other forms. I shouldn't have to buy any parts! I think this will be come a Colpits. I don't have one and it is high time I did.

Bill,
The transmitter in that article made a point of being multi-band with plugin coils over several octaves (80-20 meters--quite a stretch at the time). My digital copy isn't the greatest to see what exactly the chokes look like, but it might be an early attempt at the more familiar basket-wound plate chokes that we usually see on iron powder cores...only with and air core. I would think that the basketwound choke is more about space saving over a cylindrical choke than anything else.
As Don said, I don't think its a problem so long as its not self resonant in the range that the oscillator will function...keeping in mind that tuning up a transmitter often involves sweeping several megahertz before you get it "in band". I don't know how hard it is to blow up a choke at the voltages these single-tube transmitters use or not....my guess is that its possible, but I have no first-hand experience with that kind of excitement!

Tnx, Andy, for the info.
Firstly, you mention the coils. I was wondering abt that as well. All of our other SEO circuits use large dia. wire or copper tubing in the tank coils and usually have to be wound for each particular band. The Aero coils are of #14 wire I believe but they say that's ok. So far, I haven't seen any spec on the dia of the Aero coils.

I've only wound a few rf chokes, and they were per instructions in an article. I believe the one in my Hartley is maybe 100 turns on a half-inch dowel rod .....can't remember the wire size, but the coil is probably around 3 or so inches long. No problem with it as far as I know...at least no fire. As the article mentioned...the rf chokes 'are the usual' rf chokes....whatever that means. Is the construction all that critical? I will take a look at other circuits of the 1927 time frame and see what they generally use for rf chokes. The following is just some assumptions on my part:

>the honey-comb (basket weave) construction may have less distributed capacitance and inductance than one of vertical construction.
>its small size and low profile on the xmtr base may keep it from being influenced by nearby objects.
>altho the b-w coil may have a bit larger base footprint, vertical room would be min.
>oh, think I did read somewhere that the Q of the coil would be better with the b-w construction.

If I go thru with this project, I'll probably go with something of a vertical nature...but will continue looking for more info on period rf choke construction. I thought I might have the orig. QST in the book case, but don't, so, like you can't tell just what they look like.

Just wondering, if after construction, the choke could be checked with a GDO for its self resonance freq? Probably the best way is just to make it and try it in the circuit. I can check it to some extent, by running a neon lamp at the input and output ends to see if the rf has been stopped (at the bottom end). I'll probably have some more questions re. this project as time goes on...tnx for all replies.

Tnx agn for the nice sample....watch for an envelope with postage reimbursement.

Bill,

The transmitter in that article made a point of being multi-band with plugin coils over several octaves (80-20 meters--quite a stretch at the time). My digital copy isn't the greatest to see what exactly the chokes look like, but it might be an early attempt at the more familiar basket-wound plate chokes that we usually see on iron powder cores...only with and air core. I would think that the basketwound choke is more about space saving over a cylindrical choke than anything else.

As Don said, I don't think its a problem so long as its not self resonant in the range that the oscillator will function...keeping in mind that tuning up a transmitter often involves sweeping several megahertz before you get it "in band". I don't know how hard it is to blow up a choke at the voltages these single-tube transmitters use or not....my guess is that its possible, but I have no first-hand experience with that kind of excitement!

I have made a lot. I don't think 100 would be an exaggeration.
what happens when a choke s not good or improperly made? In a transmitter no power output and heat. Been there done that. Q should not be wonderful either it would appear. You are trying to create an unfriendly RF environment. Too large a wire size can ruin performance even if number of turns is good. Scramble winding seems to help for small chokes. One method I have usedisto take a 1/2 inch dowel and cut 4 slots in it on my small lath with square tipped bit. Spaced and width as similar as possible to the old 4 winding 2.5 type we used to see in old radios. Sort of a neg of the old design. I then fill all five grooves with a continuous winding of fine wire. probably #26 or so. In the end I wind up with a very similar to the old style multi winding choke except all the winding I have is in the grooves and wound to level with the dowels normal surface. I have one on the Monster Hartley and on the German Hartley. Both set work well.
If you don't have a lathe and few do a drill press will handle the job and a bastard file can be used to fashion the groove. Some of you have enough God-given crafting ability that would be no you would have no trouble creatng something very professional looking. I am not among you. Working with wood is not my forte however I have been quite satisfied with the results I have obtained.
How do you know of a choke will work? At first it seemed to be a mysterious deal and I was discouraged by it but I realized back when building one of my regens that I am building a coil that RF of the frequency I am working at does not want to travel through. In simple terms an RF obstacle course. Since making the first few and having success I have tried several different methods mostly with success including using the one section of an old IF coil. Sometimes we tend to over think things. Then they become big obstacles to us and always a pain. I have learned some how to struggle through and try everything I think of. That has solved my RF choke problem to the point I probably wouldn't buy a commercial one even if I could. I have a picture of one I built in the manner mentioned here. I will resize it and post it in a minute. In final analysis and in the ONLY one that matters is they work. 200 turns of scramble wound fine wire will discourage most HF RF from even thinking about making an attempt to pass through. So that is how do it and i am hoping it is somewhat helpful to others.

I see from the blowup I could have filled the holes a bit better. My aging eyes dont see well for close work even with glasses so I didn't notice this before however this choke works very well so I must have put enough on to do the job. I dip these in polyurethane after winding.

As has been pointed out by others, as long as the choke is not self-resonant at the frequency(ies) of interest, most manners of construction should be suitable. I think the "usual" at least in reference to most late 20s and early/mid 30s articles is a solenoid wound choke on dowel, anywhere from 1.5-3 in. long, 1/2 - 1 in. dia. I've made a number of them, even for rigs up to 150W (203A), and no problems. The links that follow show some of the chokes in various transmitters, including the last one of the 203A amplifier we used for Field Day this year...

http://no3m.net/wp-content/uploads/2016/04/80m-45-210-1928-mopa-e1460216524837.png
http://no3m.net/wp-content/uploads/2016/01/160m-mopa-210-210.png
http://no3m.net/wp-content/uploads/2016/05/210-865-203a-MOPA-e1462246940210.jpg
http://no3m.net/wp-content/uploads/photo-gallery/DSCF5047.JPG-resized.jpg

GDO should be useful to determine where the choke is self-resonant. W8JI also has info on a test setup

http://www.w8ji.com/rf_plate_choke.htm

When I get some time this weekend I'll dig around in the 1925-27 timeframe and see if there are some good articles on choke construction. It seems it was very common in the early/mid 20's for the choke to be rather large--2-1/2 and larger in diameter, closewound helix on a form. (I have some references if people are interested).
There are various "crazes" that happen in some of the early amateur stuff that are probably insular to the hobby. A good example is the basketweave (Lorenz) coil winding for the "low loss" tuners in the 1924-25 timeframe. The Feb '24 QST showed the 1BGF and "Schnell" tuners, and lots of people copied those designs. Those designs were widely copied by hams, and thus a craze for baketweave coils--various ways of winding them, tying them, mounting them....There was a QST article a couple months later that made the point that the basketweave really had no inherent performance or electrical benefit over a spacewound helix, and required more wire for the same inductance. In fact, the receiver in the December 1924 issue again points out that "you don't have to use the Lorenz coils"....part of this was that they probably looked pretty cool with different colors of shiny enamel wire :-)
So, perhaps there was a "honeycomb choke" design that was popular in 1927, or maybe a commercial product that was introduced (Hammerlund maybe?) that people wanted to emulate if for no other reason than it looked cool and was a departure from the old helix choke. The author of that article was the founder (or something) of "Aero", and they made some transmitters, so what is in them?

Eric,

You might try a long black or brown cloth shoelace. Clip the tips off.
You'll have a cloth tube that you run your own wire through to make
reproduction cloth covered power cable. That's what I did for the
metering cable on this transmitter:
http://w0vlz.blogspot.com/search/label/1934%20transmitter ,

Just a suggestion---unless the wooden dowel has been stored long term in a very low humidity type environment, you will probably want to bake the rod before applying wax or other sealant. Otherwise, you will simply be sealing in some of the offending moisture, that you are attempting to exclude. I suspect that a rather long term heat soak, at a moderate temp, would be best. You don't want to char the wood, thus the suggestion to use a moderate temp.

14132. Sidetracked by a Sparton 5542 tall boy

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-03 19:44:27 UTC
From: dulmagedon@...
Topic: 14132 Message: 14132

Yesterday on the way home from The Station we stopped at a small antique shop we had been in before when looking for old SW radios. They had none that day but the XYL saw a painting she liked identical to what her grandparents had in their house. I decided to score it now for her Nov birthday before I went back and discovered it was gone. We came in the door and there in front of us was a roached out tall boy (Floor Model) Sparton with shortwave.We got the painting and the XYL bought an antique East Lake dresser which took up the whole back end of the Journey. The guy knew I was interested in the radio and before I left I had wiggled him down to $30. It was pretty tough but had a replacement speaker in it and I needed one for the CGE set I was using the adapter transmitter with. I went home to think. In the mail was an unexpected cheque for $26.95. Finally at breakfast the XYL told me I had no choice. I needed a speaker , a grill cloth(this one was good) and the money had fallen out of the sky,(or most of it.) Surely I could scrape $3.05 from my piggy bank. I caved in and went and got it. The cabinet is beyond repair and the cord was rotten as was the plug but as I took it apart, other then an inch of dust, it looked decent. I told her it will probably work since it looked so bad. And In fact it does. It is going to become my general coverage shack receiver although it will lose its nice speaker and get converted to phones and pern-magnet. Even has the same final as the other , a 6f6g so it will also take the adapter if need be. So all the mods you spoke of Jim are going to happen here. Oh yeah despite being 1940 it also has a phonograph. The old pickup that used clamped in gramaphone needles. I couldn't believe it but it actually runs.

The RF choke will have to wait for another day. I am donating the cabinet to my buddies wood pile.

I am not easily alarmed so often I ignore somethings anyway however for the ever nervous in relation to the concept that line voltages have risen and may smoke your radio let me quote word for word from the original 1940 owners manual that was stapled inside this old Sparton SW radio.

"This model is designed for operation on 100 to 130 volts, either 25 or 60 cycle alternating current (a.c.). See label on back. If in doubt about the rating of the current which is available , the local power company should be consulted."

Above that is a dark letter warning which says,
"WARNING! Do not connect this type SPARTON Radio Receiving Set to direct current (d.c.)supply system as it will be damaged. Do not attempt to operate this set of the line voltage is less then 100 or more then 130."

I am sure other manufacturers saw it no different. Many used the same circuits more or less and same parts.

Don –

That is interesting. Since they tell you not to try it on DC, I assume it has a transformer. It must be a pretty hefty transformer in order to go all the way down to 25 cps. 73 – Mike

Mike,Don.
? ? ? ? ? ? ? ?I stand corrected on this, but I think that before WWII most Canadian appliances were designed to operate off of 25 cycle AC. I think it wasn't until sometime after the war that they became standardized with the rest of North America and went to 60 cycles, which continues to this day.?

If anyone on the list would know more about this I'd be very interested in hearing more about it. Does anyone know what year the conversion was and why they operated off of 25 cycles in the first place? I wonder if it had anything to do with the hydroelectric generating plant at Niagra Falls? If so, then what about the Western Canadian Provinces, etc?

Well since I have been alive it has been 60cycle but have heard some old private systems still ran 25 cycle. One might be the hydo plant at Fitzroy Habour on the Ottawa River. There is a small plant here on the Trent River which is very old but I don't know its history. The transformer in this old radio is average in size so maybe the load is light. What got my attention more was the voltage range. I had been led to believe otherwise but there it is in black and white. I know that Canada and the USA are interconnected, even in phase I havebeen told. And I know the extension cord for much of the Eastern USA is plugged in here and they get the power at less then we pay. A very sore spot with Canadian Consumers. Anyway it was the voltage range expected that got my attention.
Today I was on duty at the Ameliasburgh Museum. For many years I have been their representive fiddle maker.
It has worn thin for me so as I talked with the curator while setting up I asked about a 1920s ham radio display instead. Got a definate enthusiastic YES! So for Canada's 150th birthday (2017) I will be setting up a BK style station and operating. I am hoping that some of you would pound a little brass my way that day so it is an active display. I will buid a period correct audio amp so all can hear what I hear. It would Labour Day weekend Sunday from noon to 4 pm.

Today is BK rig day so I am making the RFC which is all I lack for the build. Starting with a dowel I elected to do it all on the table saw since not everyone has a lathe. By setting the blade depth and using a wide carbide tiped blade I cut 5 grooves evenly spaced (by eye) to accept the wire. I tapered the top so it will look official when done also on the table saw. Hopefully in an hour or so (if I can find a big enough spool of wire left in my junk box) I will have a good RFC. Most dowels are already kiln dried so mositure is not an issue.
I will predrill a small mounting hole in the bottom before doing anything else. Then dress it up with a file and sandpaper before winding.

So an hour later here we are. Connectors are made from ends of useless resistors and RFC wire stripped and soldered to them. Now for a swim in the polyerethane pot and a drip dry. Some of you would be able to produce a much nicer looking one. I seem to be more function then form. sorri.

While Don's been working on an RFC, I've been working on some plugin Lorenz coils for a receiver following an article in QST Dec. 1924, p. 52-54. I used a 3-1/2" circle of nails in a scrap of MDF for the form. The nails loosened up a bit after winding a couple, so I think I might recommend to anyone attempting this to take the time to drill holes in a sturdy slab of wood and put in wooden or brass rods if you are going to make a bunch like this. It should last forever and will probably keep the larger coils in a more regular shape.

They are wound with #16 enamel wire. 6-32 screws are inserted into a phone-tip plug to make the whole assembly "pluggable". I also found that my stash of phone-tips wouldn't quite accept a 6-32 brass screw, but I was able to ream them out enough with a Dremel tool and an old 1/8" drill bit to get a tight mechanical fit that soldered well.

The only receiver I've ever built was a solder-by-numbers Ramsey kit with a FET and PC board about 20 years ago. This is something entirely different...

It's going to be a regen with a movable tickler. The picture is of the secondary coils, hence only two contacts. The QST editors mention using a "Hartley" or "Reinartz" arrangement in which you use a tapped coil for tickler and secondary and a variable condenser to adjust feedback. This seems to be a more common plug-in arrangement later on since one only has to change one coil to change bands if you put them all on one form.

Oh I didnt realize you had seen it.
Anyway that I what I was told by an online guru at the time (about 25 years ago) who also offered to buy it.
It was a locally owned radio belonging to the Spraque Telephone Company Prince Edward County Ontario Canada. Their estate was held up for many many years (perhaps 40 or 50)until a family member capitilated or died then it was dispersed. The building was full of Antique telephone equipment , boxes of early peanut tubes smaller then WD11 or 199s , I forget the number but suffice to say I have never seen any since. When the box of parts and pieces came up no one knew what it was this little oak box with a funny looking tube and some dials cept me. I told the XYL I will go to $2500 for it but I am not leaving without it. I had to buy the whole box. Luckily for only $250. A telephone collector came to me and asked if I would sell him some of it. I told him all I wanted the oak box so he gave me $100 on the spot for the rest and I am in only $150 now. I took it home , repaired the grid leak by rewinding the resistance wiring which had started to unravel. Adjusted the condensor spacing as the box had warped a bit stressing it. Clipped a few 9 volts together and bought a 6 volt cell and hooked it up to my ham ariel and a pair of Brandes Earphones. Tuned the dial till I got the local station, adjusted the coil positions for proper feedback just in time to hear the local hockey game and our teams first score. 1917 1919 not a hill I wanna die on . BUT it is the OLDEST commercially built tube radio i have ever seen bar none and I have several with in an arm length of me right now. I was offered ("would you consider taking ") I believe $1000 US (was about 25 years ago)and I didn't even flinch! It aint leaving here while I am breathing. There is absolutely no chance of ever getting another one.

Here's an early Starr Metal Products set at the Canada Science and Technology Museum:
<http://source.techno-science.ca/artifacts-artefacts/images/1994.0241.001.aa.cs.png>
http://techno-science.ca/en/collection-research/collection-item.php?id=1994.0241.001

The Canada Science and Technology Museum looks pretty interesting. Has anyone been there?

73,
Niel - W0VLZ

Let me add my 2 cents worth re: power cable. Radio Daze sells an 8-conductor cable with a wovenbrown fabric wrapping. The only short-coming is the gauge of the wire. You will need to parallel atleast 2 wires for any substantial filament current (e.g. 2.5 volt). I installed this cable in a FBXA thatI restored. To allow for the use of either 2.5 or 6.3 volt filaments, I paralleled 3 wires for each side(for a total of 6). This left 2 wires for the B+ and ground. It's a trifle stiff but it looks OK.

14162. AWA 1929 Bruce Kelley QSO Party Notes Plus Some ..... de WA9WFA

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-10 13:26:52 UTC
From: Louis Vermond
Topic: 14162 Message: 14162

Please note the event is not on it’s traditional first and 2nd weekend in December but instead the 2nd and 3rd weekend.

Hi All, Just a September reminder of the upcoming December 2016 Bruce Kelley 1929 QSO Party! For some of us it’s time to dust off the tubes and find out if our 29 gear works 1 year later. For some on here, it’s 1929 all year along so nothing to check out or dust because the 29 gear is used all the time. My close friend Harold KB0ROB uses his 29 gear all year long so he’s got nothing to dust off. The rules and log are up on the AWA website under AWA Events/AWA On the Air/Bruce Kelley Memorial QSO Party. Thanks Tim. If you don’t use the official log sheet, at least please add up your contacts for me so I don’t have to do it :)

Please note the event is not on it’s traditional first and 2nd weekend in December but instead the 2nd and 3rd weekend. Tim W1GIG made the change based on a big CW contest blowing into the first weekend. I hope this doesn’t cause confusion. Please mention to your 1929 buddies that the dates are December 10 and 17.

I am also announcing my retirement as the 1929 QSO Party manager. I’ve submitted my resignation to Tim W1GIG with the commitment to run it in December 2016 and do the scoring and write up for the Spring AWA Journal issue. There needs to be someone new at the helm for the 2017 event. Hopefully YOU. After some 13 or 14 years of managing this fun event it’s time to pass the administration along to another dedicated 1929’er. It has been a true honor for me to run this event for the Antique Wireless Association, and more importantly Bruce Kelley and John Rollins. When I volunteered to help John imagine my surprise when I was eventually asked to take it over! Later John would send me a letter saying how happy he was with my management of the event and to keep it alive for him and Bruce. I feel l have done Bruce and John well and they would be pleased with how well their "unique in all ham radio event” has continued to thrive. Most recently I initiated the W2ICE/ special event station which has been so fun to be and work. We’ve been passing it around the country which adds to the intrigue. My thanks to the AWA and Ed Gable for allowing us do to this. It’s been many years since W2ICE has been heard on the bands until we put it on the air 2 years ago. I think Bruce would be happy. Lets face it, there is something beyond intriguing about building and operating this 1929 equipment, and you 1929’er are unique in ham radio. THANK YOU! You are the “hams ham”, building, operating, enjoying.

Just before John passed away, he was building a few Colpitts tank circuits for some close friends. The Colpitts oscillator configuration was John’s favorite. Harold KB0ROB got one, Tim W1GIG got one, and I almost got one. John passed away before he mailed it to me but Tim Walker W1GIG stepped up and mailed it to me for John, knowing it was supposed to come my way. I didn’t know about it until it showed up in the US POST Mail with Tim’s note. Thanks Tim!! Harold KB0ROB knew John was making it for me but didn’t know if John was able to ship it before his passing. There are a couple of us Colpitts “aficionados ” in the 29 QSO Party :) You should give it a try, very stable, neater than those old boring Hartley’s and TNT’s har har.

If you are interesting in taking over the event, please contact my good friend Tim Walker W1GIG w1gig@...t, the AWA Amateur Radio Manager, to offer your help! Help keep it alive for Bruce and John. Tim has been a good AWA friend and AWA Amateur Radio Manager after taking over from John Rollins. So working with Tim is easy! While he may be easy to work with, he is not so easy to contact in the 1929 QSO from this location. I've worked him a few times but I can't tell you how many times I've heard his 80 meter signal drift in on 80m in the early morning around 6:30 AM for a few minutes but fade out before I can work him :)

As I reminisce I should mention one of my favorite AWA memories is of the 2007 AWA Conference where my close 29 friends Don N9OO, Lou VE3AWA, and I sat outside of the RIT Conference Center smoking some big fat Macanudo cigars, sipping wine, and the whole time talking about 1929 radio and the AWA museum. Later Lou gave me a rare blue beehive insulator for my 29 Colpitts transmitter at the convention so I finally had a set. Earlier the peach pie with Don and Lou at that restaurant across the street from the downtown Bloomfield museum was memorable! What a fabulous time!.

Our good friend Bill K4JYS, who was the high scorer in last years QSO Party, has agreed to operate as W2ICE/4 this year, using Bruce Kelley's callsign and portable from North Carolina. Bill's excellent signal with its "character" (ok, a lot of 'character' hi hi) and superb operating skills will put W2ICE/4 in a lot of logs this year! Thank you Bill!

Lastly and on an unrelated note, I have a couple of old radio items to sell :) I have an original 20's GROWLER that is incredibly well built into a wooden box with thick copper shielding lining the inside of the box. The GROWLER is shielded oscillator used to determine a 1929 regen receiver's frequency without overloading or pulling. I've seen the circuit in the late 20's and early 30's handbooks. I believe it uses a 24A. The operator connects the Growler and tunes it until the signal is heard in the receiver. It is also a shielded receiver used to determine the transmitting frequency. Also selling an early 1930's home-brew crystal controlled transmitter built for 80 meters, on a metal chassis. Original 80 meter coil has collapsed as the plastic disintegrated somewhere along the way but I still have it. It still has it's original 1930 electrons stored in the circuitry. Also selling a unique 1930's crystal controlled transmitter build on a wooden chassis, with meters mounted below the electronics, about 3 feet long, using a 210 in the oscillator, some unknown tube in the buffer/mixer, and an 860 nuclear reactor in the final. Not sure how to ship it. I don't know if it's all original or been updated. I will let you arrange with the UPS store to box and ship it. Email for pictures and price on these items if interested.

I've sold most of my boat anchor radio gear now. Just a few pieces left to sell. Now I have a nice very SMALL collection of boat anchors that I use on a daily basis but sold nearly all my LARGE collection for reasons that I will not share here. You can see pictures of the remaining gear up on my qrz.com page. I decided not not save that mess either to move or for my estate to get rid of when the time eventually comes for all of us.

That's about all I have for now. I'll send out a reminder as we get closer.

Hope to work you in the 1929 QSO Party! 73, Scott WA9WFA=

Scott,

Thanks for all you have done with the BK event! I can certainly understand wanting to pass the baton to someone else.

I had a great time operating as W2ICE/1 last year! That is something I will never forget. I only wish I had been in better condition for it. My arm was giving me a lot of trouble and I wall struggling with the key. Some may consider it unfair, but I now am able to key the '29 rig with an iambic keyer. I am afraid I am getting to a point where operating for any length of time with a straight key is not realistic.

I am very intrigued that the BK weekends this year don't overlap one of my favorite "mainstream" contests, ARRL 160. Perhaps I will be able to operate both events this year without feeling guilty or compromising. That is, if I get some things sorted out here. Currently I have no antennas for 80 or 40 meters, but I do have a plan. Does anyone have any 48 hour days or 14 day weeks they could part with? A nice stretch of comfortable weather would help too. HI HI

73,

Paul "Bugsy" N1BUG

Tnx Lou for the re-post from the other AWA list....below is also a re-post of my comments from the other list...Bill

---

Scott, I enjoyed reading a bit of history of your experiences working as the 'head honcho' to our BK and other interesting items....be careful what ya sell....I still have a few regrets from that same thing from years ago. You sure have done a great job and will be really missed. But of course, you will still be participating in the BK and here on the list I'm sure. And also a tip-of-the-fedora to Tim as well. Our BK has been in very capable hands for a good while and am sure that will continue. Bruce and John sure started a hoot of a radio event. And of course, thanks to Ed Gable and the AWA for the support and use of the W2ICE call to pass around the country.

It will be an honor to use the W2ICE/4 call for the 2016 event. I am really looking forward to that! I will soon be ordering No-Doze, extra coffee, a few cans of WD-40 to massage into the fist and having a wax-cleaning on the ears. As time draws near, I hope those working 160 will discuss some operating times into NC. I will do my best to accommodate most any time frames. I am hopeful for good condx. Remember, I will only be running about 2 watts out to a inverted L...so you guys may have to put your ears in the spkr to hear me on 160. Eighty and 40m, hopefully will be easier. Lou, keep the count-down going....73 de Bill K4JYS

14172. Receiver Filament Leads, etc.

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-14 03:05:10 UTC
From: Eric NO3M
Topic: 14172 Message: 14172

What is the recommended / best practice for handling the filament lines in a receiver? (ie. least hum)

I've seen a number of routing methods including floating lines w/ and w/o a center tap resistor, w/ and w/o twisting the pairs. In another variation, one of the incoming filament leads is grounded, and either still routed to the tubes as part of a pair or the other end of each filament is connected to the chassis for a return.

My HRO-5 uses floating + center tap resistor, no twisting

HRO-7 appears to ground one incoming lead, only route the other lead to the tubes, and ground the other side of each filament to chassis

FB-7 looks like a pair of leads runs to each tube (twisted or untwisted?), but one of them is bonded to the chassis (B-)

The schematic for the particular receiver I'm building is similar to the FB-7 method. In this case, is it necessary to even run the grounded lead instead of just relying on the chassis for a return? Are they supposed to be twisted if this method is used?

Thanks for any insight. Just getting ready to start wiring the superhet, latest update w/ photos:

http://no3m.net/2016/09/1934-superhet-receiver-8/

Also, before I start getting into other wiring, was it common to lace wire bundles in the mid-30s or was the short, point-to-point rat's nest method still prevalent? How was it done in a FB-7?

73 Eric NO3M

Eric, Are you talking filaments as in heaters, or straight direct heating filaments? I'm no expert but I'll tell you what I found in my Mk.26. The filaments (heaters) are all powered by DC. I originally ran only the + lead to the heater terminals and grounded the other side to the chassis. It worked well enough, but it was picking up an annoying hum. I decided to isolate the DC heater supply and run two leads to each tube socket, with a pot across the circuit, going to ground through the wiper. Result; no hum at all now. Directly heating filaments usually like DC on them, and if you read the tube manual carefully, you'll sometimes find that a prefered polarity is usually recommended.

Leonard

The tubes are indirectly heated (56, 57, 58, 2A5 or 76, 6C6, 6D6, 42). I'll be running them from an AC supply. What you describe is similar to how my HRO-5 is wired, w/ center tapped resistor across the filament circuit and both sides of filament supply to each tube (indirectly heated tubes, 6K7, 6J7 variety).

Are the filament leads twisted in your Mk.26?

Thanks
Eric

Last night as some of you know was part of the Classic Exchange CW event. My friend Andrew GW3OQK suggested I pick one of my old rigs and we see of he can hear it during the event. He assigned me a freq and gave me a time slot.. I said I would try the 211 Hartley. So I did. He said he heard me tune up (key down to warm up everything then touch up freq). At 2313 he heard me calling and even managed to record enough of it to clearly hear my Hartley and my ID plus K. Says he has it on MP3 format. I am surprised to be honest. I figured I was just sending onto a black hole. He is a retired Ships Sparks and a technician as well. His ability to find you is amazing. Also heard he picks a mean banjo. (Andrew lives in Wales)

Tis the longest 29 rig haul for me at just over 3200 miles ATCF. I am just a wee bit excited . Sori.

Topic: 14172 Message: 14178

Eric, the filament leads in my Mk.26 are just randomly laid out. Since it's DC I didn't see the need for twisting them. Besides, it would have required a major rewiring. For AC leads I think it would be necessary to twist the leads. Also, another thing I did on some of my other sets, was to have a distribution point and run all filament leads from that point to each socket. The leads should be tightly twisted and of equal length. I doubt if this will solve all problems though, because there's so many ways hum can get into a circuit. But DC'ing the filaments doesn't hurt. My RAL-7 had a bad hum that I couldn't get rid of until I rectified the heater supply. Also, some tubes are more prone to hum pickup than others. Sometimes reversing the filament connections can help.

Leonard

Subject: Re: [AWA Group] Receiver Filament Leads, etc.

Leonard

The tubes are indirectly heated (56, 57, 58, 2A5 or 76, 6C6, 6D6, 42). I'll be running them from an AC supply. What you describe is similar to how my HRO-5 is wired, w/ center tapped resistor across the filament circuit and both sides of filament supply to each tube (indirectly heated tubes, 6K7, 6J7 variety).

Are the filament leads twisted in your Mk.26?

Thanks
Eric

Eric, Are you talking filaments as in heaters, or straight direct heating filaments? I'm no expert but I'll tell you what I found in my Mk.26. The filaments (heaters) are all powered by DC. I originally ran only the + lead to the heater terminals and grounded the other side to the chassis. It worked well enough, but it was picking up an annoying hum. I decided to isolate the DC heater supply and run two leads to each tube socket, with a pot across the circuit, going to ground through the wiper. Result; no hum at all now. Directly heating filaments usually like DC on them, and if you read the tube manual carefully, you'll sometimes find that a prefered polarity is usually recommended.

Leonard

I was on 40M. Andrew GW3OQK who spent much of his working life as a Ship Radio Officer has proven to be someone I can work with. When he suggested it I thought it worth a try anyway but didn't expect too much. He told me to set up on 7045khz and to listen on 7039khz as for him 7045khz is sometimes digtial from Europe. So I did. Time of the recording is 2313 UTC. I believe I was perhaps a 1/2 kc off the 7045. He has it all. Andrew is a very good operator and if here were such I would award him the Honour of the Golden Earphones. He is tenacious when signal hunting and has good vintage equipment and knows how to run it. He is the reason it was a success. Like that addage "if a tree falls in the forest and no one is around does it make a sound?" With out an Andrew listening on he other end faithfully, exactly where he said he would be the answer would be "no." The 211 is running about 1/2 throttle voltage wise which I think is prudent for such a design. Power input is close to 20 watts so not huge. Antenna was a 137 ft single end fed long wire and I also ran a ground. (I don't always)

I like to run separate, twisted leads, with a pot across the heater supply with the wire grounded.

Separate leads (rather than grounding one side of each heater to chassis) keeps 60-cycle currents off the chassis, which can and do get into grid circuits, and amplified. Sometimes this requires each filament lead to be RF-bypassed to chassis ground in RF and oscillator stages.

Twisting the leads helps cancel both electrostatic and magnetic fields around them.

The pot helps find the optimum place for minimizing any residual hum.

If you really want the least possible hum, run well-filtered DC to the heaters, but often this is more trouble than it's worth. It's OK for a 1-3 tube set, but for something like what you're building it's not very practical due to the large amount of heater current, especially in the case of 2.5V tubes.

Running AC, I'd expect less problems with hum with the 2.5V series tubes than the 6.3V, based on reports from back in the day of the transition from 2.5V to 6.3V heaters.

Great Idea. I hope you find a suitable one. Lou has an all British design that I think is quite good. I have a German one which is Hartley or dreipunkt based. Both Lou's and this one seem very stable although I haven't run mine much on air. (Why? I have no good reason) Whether it would reach the UK or Europe I don't know. I just tested it then shelved it. An intercontinental BK style event would be special. Maybe on the Marconi transmission anniversary night. It could be called "The Marconi" . I know,I get carried away :>). Sri.
Anyway I have become more and more interested in single tube pond hopping and have been seriously thinking about something like a 811 (or a 211) rockbound rig running full power on 20M. Sometimes when I am in the Vintage shack I listen around. There is an F5_ _ _ on CW that is often good copy here.
But with the pre 1930 rigs It would be special. I hope you come up with a suitable one.

From: Bill Stewart
Topic: 14194 Message: 14194

GM all,
I am aware of various materials (Garolite, etc) for making terminal strips and other parts but just wondering about using some composite flooring I had left over. It is very hard, dense and stable. I have used it for a couple of panels and a base or two with no problems. Painted with wrinkle paint, it looks pretty much like a metal rack panel or Bakelite, if just black. I am thinking about using it for mounting some fah. clips or screw terminals for a BK type rig. I would paint with black spray paint to 'look like' Bakelite. Seems I heard years ago that carbon was used to give it the black color. Is this still being done. Would spraying this 'flooring' material with the black spray paint cause any problems at, say, 500vdc or less and at RF voltages in the neighborhood of 20 watts or so. I could do some experimenting, but just curious if anyone had tried something like this and what were the results. Thanks, 73 de Bill K4JYS

Hello all;

In Tom Peterson?s recent letter to the membership, there is an URL for
an AWA survey. While this URL is technically correct, there is a great
tendency to interpret the last two digits of this URL as the number 21,
when in fact the last two digits are ?2L? !

If any of you have had no success in accessing the URL, try this:

https://surveymonkey.com/R/3SZVY2L

The web doesn?t care if these letters are capitals or lower case!

From: Roger Kuchera
Topic: 14204 Message: 14204

Gentlemen, Sometime ago Tim/W1GIG asked if I would volunteer to moderate the 2017 Linc Cundall event. I haveaccepted the task with some trepidation. I have never, in my 44 years as a ham, done anything like this. Ihope that I'm not biting off more than I can chew.

The present format and scoring seems to work, so there should be no reason to change them.

I hope our league of extraordinary gentlemen will bear with me as I try to learn the ropes.

Roger/K1TG

14209. Interesting Variable Cap -

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-23 02:32:18 UTC
From: Mike Feher
Topic: 14209 Message: 14209

I have never seen one of these before, or even knew of its existence in my over 50 years of collecting old radio stuff.. The rotary part kind of serpentines into the stationary part as the knob is rotated. There is probably a better word for it and my choice may be totally wrong, regardless, it is an interesting cap. Check it out. Regards - Mike

14213. 1916 Aero radio station

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-26 15:11:34 UTC
From: dulmagedon@...
Topic: 14213 Message: 14213
Attachments: 1 described; binary payloads are missing from this source WARC

I came across this. It is reportedly a very early WW1 military areoport radio communication centre when radio first made it in to military aircraft which were simply observer planes. They said this was a major improvement to have live reporting rather then wait for the plane to return for info. I know no more then that. Not a great photo. Still very early use of radio in aircraft although this is clearly the ground station. The date given for this event was 1916.

14214. BFO Alternative Thanks

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-09-28 16:28:57 UTC
From: dulmagedon@...
Topic: 14214 Message: 14214

Thanks James H for teaching me about the alternative method of adding a BFO. I have been experimenting with it quite a bit and have a usable one installed on the old GE parlour radio and today just finished up reviving a Sparton 5542 (1939-42 approx) I am now able to add it from the top easily and have it work well. If you hadn't mentioned it I would never have known. Thanks and "May you live an extra day."

Topic: 14215 Message: 14215

GM All,
Great news for followers of the Maritime Radio Historical Society Coastal Station KPH /KSM:

MRHS Newsletter No. 57
EXTRA! FLASH!
Special Edition - KPH Comes Home!
Date, Time and Details for Resumption of KPH Service!

Please see this link for all the info - freqs - times. etc for the special on-air event to welcome KPH back to its original frequencies:

http://campaign.r20.constantcontact.com/render?m=1109843077277&ca=c70b9439-141a-41ad-84fb-8d1840a8e2e6

Fire up those BA receivers and modern ones as well and join in the return of KPH to it's original frequencies.

Scott

I picked those up on Ebay almost two years ago. Only needed a couple for an HRO project, the rest sat in a box until now. I was glad to have them on hand! GL with your search; Ebay prob your best bet unless someone on the list has a stash or you can find a junker HRO that has that style (Senior? and maybe early 2.5V HRO-5).

Hello friends,

when I showed up here in this group some weeks ago, I showed some of my spysets. Mike, N4FS, said: Your "Sweetheart" is a bit like the "CMS". I had never heard of that set before. After getting the first infos, I licked blood. I could not make a 100% replica, as the interstage transformers for the receiver were not available. I used the sweetheart schematic, and the 3-way switch is bandspreading for 60/40/30m. The worm gear has 1:100 ratio, so the tuning behaviour is really nice and soft. 60m is said to come soon in Germany. The tone of the TX on 60 and 40m is fine, using FT-243 or 19mm Czech crystals. On 30m I only own small modern crystals....here the note is pretty "vintage".
We can regard this project as a direct result of joining the group. So thanks to Don for inviting me and to Mike for attracting my attention.And special thanks to Al Klase, N3FRQ from http://www.skywaves.ar88.net/ http://www.skywaves.ar88.net/ who supplied excellent pictures and made this replica possible.

Great buildTom. We should try a pond hop! My soldering iron has been smoldering too. This is for 40M and doubles on 20M (I hope). About 75% from smoke test.

I am waiting for a small parts order but all that is left is to couple the cyrstal osc to the quad 4 output and those are the parts that ordered a week ago. So I did the smoke test as is. Ok. Five 25L6s in AC/ DC mode (aka transformerless PSU) . First is crystal osc running on 40M driving the four other tubes that are running as a quad four PA which is also set up to be able to double for output on 20M if desired. It is experimental but I am hopeful as similar designs (original longfellow) have been done in the past. We shall see soon I hope. It is our Thanksgiving weekend so there will be no mail or parts till next tuesday. Oscillator is always on. PA screens are keyed and backwave protected. Power in is moderate and typical as the tubes would normally run on. Plate current is monitored by my favourite device, a pilot lamp. I will have to entertain myself with the other rigs this weekend. I had hoped to have this one running. I will have to kill the osc on rec I think so a stndby switch will be in order.

Done! I wasn't going to use any used parts on this build but I didn't get my order after over a week and it is coming from just 100mi away so this morning I dug through my junk box and found the three parts I needed, trimming their leads to remove evidence of previous use and soldered them in. They were not exact but in the ball park parts. I plugged a set of 40m crystals into the socket. (it holds two) A 7140 and a 7145. I turned on the power and waited for warm up i could hear the osc in the monitor rx and after keying and tuning the PA cap got a decent signal on 40M. The screen keying seems very smooth. I hear no chirp whatsoever. Since it is running on around 130 volts B+ power is not huge but this is a "for fun" build fed by having the idea of using five 25L6s in a TX. The crystal selector switch has three positions. Down , up and middle. In middle there s no connection so the osc stops. It works fine for a stanby switch. I hadn't thought of that before. The crystals are a bit high but for what I made it for (coil wise)but the 7140 which shows 7138.6 on the monitor RX (DX394RS) Seems especially happy when tuned up. I will probably play with it this afternoon just for something to do. I will do the final rubbing on it when my order comes and i can optimize the parts I was waiting for but for now it works and doesn't seem to be hurting itself. So I now have my own Longfellow. I haven't had it on the air on 20M although on the dummy load it appears to work.
Kind of a fun build. Wood is maple BTW.

I'm getting ready for BK with a two-tube (#27) Hartley. I tore it apart after getting it working in April and want to make it ready for 160/80/40 with separate plate coils of identical OD. It will be link coupled to the antenna using an LC network. There must be some rhyme/reason to choosing the link. Can someone please point to some information on link coupling design? What information must be known in order to design the link?

To date, I've just been using "several" turns of wire and....it "works" via the principle of magic! Having one link coil would make life easiest but three is no problem if squeezing an extra db is possible :)

Thank you.

73, Dean, NW2K

40M 2 turn link, 80M 3 turn link. 160M I don't know but would try 4 or 5 turns. More is not better. Output is noticeably different. You could fudge 40 and 80 with a 2 1/2 turn perhaps but to work on 160 would be too much of a stretch perhaps. And your antenna makes a difference too. Old books (ARRL Handbook for instance) tell you to start with x and experiment. I use light bulbs to find the best combo and sweet spot. Unlike meters they never lie. Might not be as others would do but that is how it is determined here. Tis hard at first to realize so few turns works better.

Dean - if it's of any help to you, my B&W 160m coil with built-in (supposedly 50 ohm) end link has 3 turns on it. When used on my Longfeller I could only get 5 watts out of the 6V6 on 160m and 7W out with a 6L6. I doubled the link to 6 turns and the outputs went to 11 and 14 watts respectively so it's clear that 3 turns is not optimum. I did not try any more than 6 turns as I couldn't realistically expect much more power than what I was seeing at that point.

Dean,

IMHO, setup a "foundation" for the tank coil complete with appropriate link. Once set up for each band there will be minimal time lost in changing bands.

Tweak each coil set using a known resistive load (Cantenna?). Use an antenna tuner known to load what ever is hanging outside and mark tuner settings for each band using live prior tests when band is "dead". I would think that is about the best preparation that can be done, aside of a couple of spare tubes, rectifier and lots of coffee...

Many years ago I cleaned the last of "obsolete" stock of a local distributor. Amongst that stuff was a group of B&W Ham tank coils and links. These appear to be in the 10 to 50 watt range judging by size. Some are in original boxes with part numbers, some are open style and others shielded. Unfortunately I do not have any vintage catalog to reference what coils go with what link.

Anyone know where I can find an on-line vintage B&W catalog it would be helpful..

I have not built my "B-K" and Bruce has been haunting me for many years :) He continually shames me to get to practice my almost non-existent CW too...

I have a "vintage" TNT breadboard rig built by a local S-K some 40 ya with a 10 in it. It is a conglomeration of parts sprinkled with Phillips screws and a couple of"modern" resistors. I got no idea if it works,I do suspect it is on 40 but never got the courage to fire it up. I live in a land dense with O.O.'s...

GL with project.

Thanks to all for the suggestions. I started with "more is better" and used a link with about the same inductance as the tank. Tone and stability were great and the device was a pleasure to use to make Q's at about 1w out. The link was certainly not optimized and I still don't know how to think about the link design rules.

I found a page by W8JI on link coupling (http://www.w8ji.com/link_coupling.htm). I don't understand it yet and trial/error sounds like it might be easier!

I received some excellent suggestions and I'll pair up three links with my three primary coils. All of my antennas are well behaved (50 ohms). I need to move past my sliding v-block arrangement and fab some sort of band change mechanism.

Thanks! 73, Dean, NW2K

I see. You are looking for an engineering style rule. The ARRL books clearly state to do the trial and error adjustment after initial build. There are a lot of variables. I have been working on my Longfellow today and was able to more then double power output by playing with it. Placement being as important as No of turns. However number of turns in the tuning coil over pi (NT/pi= link nt) where NT is number of turns in the tuning coil and pi is 3.14 and link nt is number of turns in the antenna link will get you mighty close. You will of necessity have to fudge to the nearest full turn more or less. However it is easier and quicker just to whip one up and test it with a light bulb. The power hidden here as Steve already indicated in his post is nothing to be ignored. Sometimes on a QRP rig it is the whole ball game. It is as he showed clearly well worth the effort.

I really like those copper coils! Cool!
I am going to say about more about links that I have learned. You may already know all this so if so forgive me.
Sometimes a link can be too efficient. Even though it makes great power it pulls too hard on the OSC and occasionally some won't start or are stubborn. Sometimes a variable cap in series with the centre lead will help out but I now often put on and extra turn or leave part of one off from ideal so as not to overload the OSC. Or if the coupling is movable you can just move it to a less coupled spot to give it some ease. Not so much a problem with a mopa but a single stage self controlled OSc occasionally can give trouble there.
Lamp indicators. I use 4 6 8 and 10 watt incandescent lamps installed as dummy loads when trying to optimize my links. I find it very helpful. Meters other then thermocouples or purpose built have trouble in a heavy RF environment and sometimes the readings are bogus. The lamps cut through the bull and tell you plain and simple is it putting out. Is it strong weak or whatever. I trust them. Maybe that seems simple and old hat, however it does work and never lies.
Anyway Thanks for your pictures. I see you are certainly having fun. Great Hobby!

Help,

Does anyone recognize what National radio this tuning cap. assy. came from and/or what kind of dial was supposed to be used with it? It has a 10:1 geared drive with a 1/4-in diameter shaft for a tuning knob, but no visible place to connect a dial or dial pointer. It does NOT have the correct configuration to accept a PW dial. The tag that came with it says 10 pF to 245 pF straight-line frequency.

The stamped metal gearbox suggests WW2-era production, and if not a PW dial, then perhaps something in the NC-200 family?

Leonard,
Thanks for the info, but it can't be for an RCF as the RCF has the classic die-cast gearbox with PW dial as shown in the attached photo from Western Radio Museum.
My var cap's gearbox appears to be brazed sheet metal and it doesn't have the eccentric outer shaft used with the PW dial.

Subject: [AWA Group] National Var Cap [1 Attachment]

Help,

Does anyone recognize what National radio this tuning cap. assy. came from and/or what kind of dial was supposed to be used with it? It has a 10:1 geared drive with a 1/4-in diameter shaft for a tuning knob, but no visible place to connect a dial or dial pointer. It does NOT have the correct configuration to accept a PW dial. The tag that came with it says 10 pF to 245 pF straight-line frequency.

Steve,
NC-200 looks close, but not exact. Looks like my var cap must need an additional gear-set or pulleys and string to operate a dial.

The stamped metal gearbox suggests WW2-era production, and if not a PW dial, then perhaps something in the NC-200 family?

One caveat with regard to the use of incandescent lamps as a means to optimize the number of turns on the link, and the degree of coupling (physical distance between the link, and the "cold" end of the tank coil). The lamp's resistance must approximate the impedance of the load (antenna), that you will be using with your QRP xmtr, or your results will be bogus. A #47 lamp has a hot resistance that is close to 50 ohms, and will serve as a suitable load for a xmtr with a power output of 1 watt. 4 such lamps in series-parallel, will be suitable for a xmtr whose output is ~ 4 watts, etc. If you attempt to use a 7 watt 120 volt lamp, as a load (resistance in the neighborhood of 2100 ohms, and optimize the link for max brilliance (optimum impedance match), with such a load, the Z match will be far from optimum, when you attempt to feed a 50 ohm antenna system. Also, note that the resistance of an incandescent lamp varies considerably with filament temperature, so you want to use a lamp (or array of lamps) that will be illuminated to appx normal brilliance, or be prepared to make compensation adjustments.

While that is all true a 25 watt bulb is also a decent load. However while I realize it may not be the perfect way it will get you a long way down the road to on the air. An RFsniffer is another valuable tool. It appears to be effective. A thermal coupled RF meter would be nicer but $$$$$$$$

14252. Regen filament polarity and other questions

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-10-14 14:29:23 UTC
From: aflowers@frontiernet.net
Topic: 14252 Message: 14252
Attachments: 1 described; binary payloads are missing from this source WARC

I got a prototype of my 1924 SW regen working well enough to actually hear stuff, and I'm now looking at ways of improving the performance while staying true to period practice. I started as anyone would have done in 1924--building from a magazine article. Now that there is life in the phones I'm looking at how to make it as good as it could reasonably be, with the understanding that only so much is going to come out of 90-year-old parts and no shielding in a modern RF environment!

I've attached the schematic. The tickler is movable, while the primary is not. All three coils are plug-in replaceable per the Dec '24 QST article which allows lots of flexibility when it comes to experimenting. I'm running both tubes off of a common 45VDC plate supply at the moment, but I did add terminals for separate B+ for the detector and amplifier stages so I can find the right mix. Right now its a pair of UV-201A's (with 2M grid leak), but I could sub in 99's easily enough as that would also be 1924-appropriate. A UV200 in the detector slot is another possibility, but I haven't started down that path yet.

I have a couple of questions for people who have been to this rodeo before:

1) The original schematic I followed has the detector tube's A- attached to Ground/B- with the A+ attached to the filament rheostat, but in other designs I see the A+ is grounded and the filament rheostat is in the A- lead. Does this make a difference? I've attached the original schematic I'm working with for reference.

2) There is no RFC on the plate of the detector. There is the primary of the transformer and a bypass condenser, but I'm not sure that is "good enough".

3) In a transmitter I usually need a series condenser to get a good coupling to a 50 ohm antenna. I'm thinking the same is true here, provided of course that I don't over couple and cause the detector to stop oscillating or have the antenna swinging mess up reception.

Thanks,Andy K0SM/2

> An RFsniffer is another valuable tool.

Indeed it is, especially if it is tuned. One of the first things that I built at age 15, was a tuned sniffer, with plug in coils and I have never stopped using it. Getting my Tri-Tet-Ten working with its 40m crystal would have been very challenging without it as the relative strength of each harmonic could be easily checked. Even slight tweaks of the cathode tank made large changes in unwanted harmonic content on the way up to 10m.

Hello Andy,
? ? ? ? ? ? ? ? ?I'd like to see how your configuration worked out with a 00-A gaseous detector and 01A as the AF/ amp. My own experience has been sometimes they work better and sometimes not. Also, why not try a 199 detector while retaining the 01A audio amp? At least one particular "National-Browning-Drake" schematic I've seen recommended that type of configuration for a "N-B-D" receiver. I'd retain the 01A as the audio amp since it would work better than a 199 would unless you always plan to use it with a set of cans. Then it probably wouldn't make much difference.

Just my thoughts on the subject.

From: Roger Kuchera
Topic: 14264 Message: 14264

Gentlemen, I attended a local hamfest yesterday and came upon a set of oddly named headphones, namely "Little Tattler."I couldn't resist the name, so I brought them home. The cords were badly tattered so they couldn't befield tested. I installed a new cord. Lo and behold a 1.5 volt battery makes both headpieces click loudly. With a bit of soap and damp paper towel they'll clean up nicely. Some auto wax and they will go on display.

I looked up the name and the best info I found, so far, says they were made in Marinette, WI sometime between1920 and 1926. The coil resistances average 750 ohms, so I assume they are Hi-Z type. One of the sounderdisks is missing about 20 % due to corrosion. I stuck a disk from a of Connecticut 1500 headset in and it seems towork.

Is their anyone in our august body who can add anything to what I found?

Roger/K1TG

14267. de K1TG - Meter needed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-10-20 15:37:51 UTC
From: Roger Kuchera
Topic: 14267 Message: 14267

Gentlemen, I am on the hunt for a particular panel mount voltmeter. Namely, a Weston Model 506 or 517. The fullscale reading I need is 500 DC Volts. I mention Weston types because I have a 0-100 mA, type 506 infront of me. Any make will be fine as long as it is the small format type.

The approximate mechanical measurements of the small type 506 are:

2.585" - Flange diameter 2.250" - Case (panel hole) diameter

The mounting holes are the standard 120 deg. apart. The case material appears to be black Phenolic.

I would be willing to buy or swap for just about any meter I have in the "olde junque boxe." Just tell mewhat you are looking for or remuneration.

BTW: I know the 500 Volt scale can be made from lower value Voltmeters or the use of a mA meter. I am trying to avoid tolerance problems

Thank you for taking the time to look. Take care and stay well.

Roger/K1TG

14268. Ideas on stuffing/cheating interstage audio transformers

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-10-23 18:22:46 UTC
From: aflowers@frontiernet.net
Topic: 14268 Message: 14268

I'm looking for some advice on how to resurrect/reuse some burnt out audio transformers that have one or both windings open. I'm looking at ways of stuffing them so that I can reuse the shells in a functional piece of equipment that looks right on the outside. This is a ham receiver--I really don't mind having "distortion" that makes for a bandpass filter as I'll be using it primarily for CW reception. In fact, I've read of people in the old days using a pair of 6:1 transformers of the same model just to get an audio bandpass filter of sorts for CW work--opposite of what you might do if you wanted to listen to music.

1) I know some people have stuffed the shells with resistors and a cap for resistance coupling, but I'm concerned that I'm not going to get much gain when using a low-gain tube (UV 201As, supposedly with a mu of 10 when new). Ultimately I'd like to drive a Hi-Z horn with two stages of AF. I'm not sure RC coupling will get me there, but maybe I need to try this. If anyone has had success with this I'd appreciate some component values as a starting point.

2) Are there "small" modern replacement bobbins that I can either slide on the core of the old transformer or use in its entirety to fit inside a shell if small enough?

3) How about running a 60's-vintage "transceiver transformer" backward? I'm not quite sure what the original application was, but I have a stancor A-3836 that says:

Primary 10,000 ohms (30ma)Secondary 2000 ohms and 50 ohms

Crazy thought: is there any reason I couldn't swap the primary and hi-z secondary and get it to behave something like a 5:1 AFT? I bring this up because I have one and I can probably just fit inside the shell of one of the larger AFTs to hide the evidence...

Andy K0SM/2

I recall seeing an active (with transistors, forsooth!) circuit in a
past AWA Journal or OTB that IIRC was used to replace step-up audio
transformers in old broadcast sets. I can't give you the issue, but iot
was probably in the past 10 years or so, I think in one of the regular
restoration columns.

Not that I know of, but have you checked Antique Electronic Supply Co.?
I remember seeing audio interstage transformers, but don't know if they
still carry them.

I see no reason why that transformer wouldn't be perfect for the job.
The plate current for an '01A is probably not enough to worry about core
saturation, even if the replacement wasn't meant to carry DC through one
of its windings.

Hi Larry, I'm not sure how appropriate this tidbit might be but I have had some success in using 6.3 and 12.6 volt filamenttransformers as couplers from plate to headphones. Some of the old Radio Shack transformers are CT on thefilament side. They are relatively small and some have a steel shell. Just a thought. I have no idea what the mis-match might be. I'll do almost anything to keep B+ off my headset....I hate surprises! BTW: That would be the 115VAC winding to the plate and filament winding to the cans.

Hi Roger,

Just in case you didn't know, I was attempting to answer the questions posed, I was not the original poster. That was Andy, K0SM.

120VAC primary/12.6V secondary filament xfmrs provide a decent match as a 500 ohm-to-voice coil transformer, and I have used them as such. A 6.3V filament transformer theoretically, then, may be able to match a fairly low Z (2K ohm) to voice coil, but watch for saturation of the core if the DC current through the primary winding is significant. To match Hi-Z phones you would want about a one-to-one ratio; again, beware of saturating the core. As I said, you probably don't have to worry about this if the current is low - say, 10 mA or less (admittedly a SWAG on my part).

AES and Radiodaze sells (sold?) them, and also just the the windings without the core. They must have been pretty cheap because I bought several of them. I think they were made by Hammind, although China may have been involved, IIRC..

14278. Wireless Set No. 19 info needed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-10-26 02:08:58 UTC
From: Roger Kuchera
Topic: 14278 Message: 14278

Gentlemen, I gather from emails, that there are quite a few WS 19 owners in AWA land. I recently acquired a meterwhich seems to be from a WS 19 (a SWAG on my part).

The front panel scale is 0 to 600 Volts. The meter has NO multiplier resistor in it. A 1.5 Volt batterybangs the pointer on the end scale stop.

Here is the nomenclature found on the meter face:

W.S. NO. 19 VOLTMETER MODEL 125 6323

There is an ink stamping on the magnet: SEP 7 1944

Here is the nomenclature found on the rear of the case:

CALIBRATED FOR USE ON STEEL PANELS

2% Hi

15937 622.J

The scale is phosphorescent (Radium paint?).

Can any of you gentlemen give me the multiplier value or let me know where I might find the info ora parts list/schematic? I would be obliged. Thank You!

Roger/K1TG

From: Don Dulmage
Topic: 14278 Message: 14279

Yes that is correct. The resistors used to let the meter read each scale are external and are just normal carbon resistors and were notoriously bad for value change. I have replaced most of mine to bring the readings back in line with real values. I have a schematic for a MKIII Canadian Set if you would like it . The PSU delivers about 575volts and runs at around 550 to 560 underload. That is only feeding the single 807. The lower HV for all other tubes is a nominal value of around 275 volts . Also it reads the battery or heater voltage and the AVC which is a good enough reading that you can tune the antenna on RX and it will be right on the money for TX. It also reads antenna current backwards from the external antenna tuner. Mine is 1943 and I have a twisted needle but it still works.
If you would like the schematic email me direct.

GA Don, Thank you for your response to my question. I was looking for the easy way out by asking for themultiplier value.

Yes, the carbon composition resistors do have a bad reputation for value change. I use metaloxide types as they are very stable. I am not looking for absolute accuracy but something within 5 or10 percent would be good.

My application is for a Voltmeter across a regulated 300 Volt supply, so this meter is nearly aperfect fit mechanically and electrically.

What value did you replace your resistor with? In a parts list I found on the net there are 2 valuesmentioned as meter resistors; 1.2 MegOhms and 29 KOhms. I don't know if they are the resistors Iam looking for.

Your help is appreciated. Take care and stay well.

Hi Don, What you sent me was not translatable. It was a series of alphanumerics and formatting data.I hate to be a pain. Try again?

What I found online was from another VE3 (VE3BRB ?). It showed the following:

R24A - 1.2 MegOhms, 5%, 1/2 W. R25A - 1.2 MegOhms, 5%, 1 W. R26A - 29 KOhms, 2%, 1/4 W.

The schematic was very grainy when I blew it up and very tough to read. I assume a switchselects the meter function; 0-15 Volts and 0-600 Volts.

I dont remember. It was a couple of years ago. I got the values off the WS19 website but had to fudge them to get the meters to read correctly in sync with my voltmeters . Me I would use the large one first and see where that takes you. At least you wont hurt it. The Canadian sets use a different value I believe . Yes I use mine as a general reference only but it is mighty handy all the same. I will look up my values next time I am in the shack. don Ve3LYX

This might sound really stupid but my brain works from left to right. When I was sorting out the sets built in power hobble I reversed the that schematic on my screen and was able to read it much easier. Might not bother others but for my square head right to left flow didn't work. Anyway glad you got it. Hope all goes well.

I have been having a ball with my Longfellow 5X25L6 transmitter today. After getting it done and some on air testing and some feedback I have been working hard to get it to produce a real good signal. The screen keying worked but some of the osc leaked thru on key up as it ran all the time. I got it down to a pretty good spot but it still wasn't as I wanted so I hard wired the screens and tried keying the osc cathode. Worked good but I hadn't built a park circuit for the 4 PA tubes (usually 400ohm will back it up on rest) as it hadn't required it. This afternoon I swallowed hard and cut the feed and added the PA cathode to the keying load. It works very well .No clicks no chirp so I am told so I am happy. It is a fun rig to use. I have spent several hours with it today. I am now satisfied with it. I have been able to work stations in the 250 to 400 mile range today. I am working on a 20m version with VFO but am not rushing. I will use what I learned with this 40m one. The XYL gave me a small slat wood basket about 8 or 9 inches long so I am also on the side building "The Pigmy" (5 6aQ5s)
The XYL is at a hen party tonite so I am banging away on 7052kcs. (Also have 7030 , 7040 and 7045)

You might not recognize me. My CW is coming back to me. I thought it never would.

And if I dont fall asleep after midnite I may put the fire to the monster hartley. It is under the max power range and does a good job for me. Who knows? I might work Tom. It certainly came through for me a few weeks back doing the pond hop with GW3OQK. On a good night a few hundred more KMs may be possible.

14301. Auto keying for tests.

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-03 21:16:46 UTC
From: dulmagedon@...
Topic: 14301 Message: 14301

Often when building I get to the first on air test and it becomes a difficulty. I need someone to either run the rig or take a portable for some field strength tests. Having some one run a portable is about hopeless. The other alternative, having someone press the key is questionable at best unless another ham is visiting which is ideal.
I needed something to key the rig while drove around the lake checking the signal. I use pilot lamps for current indicators. I realize many don't but I do because in the event of a problem the lamp with perform like a fuse and save your bacon. Also the values are about perfect but back to keying. It is Chrismas time soon and my wife likes lots of lights. She doe not like blinking lights though so has had be remove the blinkers from all her lamps. So today i took a blown #40 bulb, removed the dead glass bulb from the socket and soldered in a push type Christmas lamp socket. I tried several blinkers 2.5 V 3.5 V 6 V and 12Volt blinkers. All available at Walmrt for about $1.25 a pack. The packsare marked replacement and say nothing about flashers but the first two in every pack are the blinker lamps. (from the left) I installed on in the longfellow and instantly i had the rig keying nicely n a more or less steady rhythm. I bricked the Key for this. Then i thought most of my rig are cathode keyed so I installed the lamp across the key (old indicator lamp reinstalled.) It worked very well. As long as tests are as short in duration as practical itis like have an extra person around to help.

BTW tested the Pigmy today. using a 35795 colourburst crystal it appears from tests to be doing good job. I need two more tubes as one is nearly dead and I am short one anyway . They should be here tomorrow although I have been operating with the OSC and two good tubes.

(Wish I had five 813s and sockets ;>)

Great idea, Don. Thanks for the tip. Now if only you could get it to ID for you in CW ;-)

I have to think there must be a computer program somewhere that would send a continuous loop of CW out to a USB port (or maybe the RS-232 port on an older machine) that could be used to actuate a relay for this purpose. One application would be for a beacon, which, essentially is what you would be operating (at least for a brief period). Another thought - I'd be surprised if someone hasn't written such code for an Arduino. It would be a trivial matter to make an interface to key the rig from an Arduino output.

I love the simplicity of your solution; the only problem I see is if your test needs to run longer than the legal ID period.

Back in the mid 60’s I designed myself an auto CW ID unit. It used logic flip flops out of which I made a shift register and then gates to decode my call from the registers outputs. Speed could be varied by varying the clock rate to the register. 73 – Mike

Great idea, Don. Thanks for the tip. Now if only you could get it to ID for you in CW ;-)

I have to think there must be a computer program somewhere that would send a continuous loop of CW out to a USB port (or maybe the RS-232 port on an older machine) that could be used to actuate a relay for this purpose. One application would be for a beacon, which, essentially is what you would be operating (at least for a brief period). Another thought - I'd be surprised if someone hasn't written such code for an Arduino. It would be a trivial matter to make an interface to key the rig from an Arduino output.

I love the simplicity of your solution; the only problem I see is if your test needs to run longer than the legal ID period.

Often when building I get to the first on air test and it becomes a difficulty. I need someone to either run the rig or take a portable for some field strength tests. Having some one run a portable is about hopeless. The other alternative, having someone press the key is questionable at best unless another ham is visiting which is ideal.

I needed something to key the rig while drove around the lake checking the signal. I use pilot lamps for current indicators. I realize many don't but I do because in the event of a problem the lamp with perform like a fuse and save your bacon. Also the values are about perfect but back to keying. It is Chrismas time soon and my wife likes lots of lights. She doe not like blinking lights though so has had be remove the blinkers from all her lamps. So today i took a blown #40 bulb, removed the dead glass bulb from the socket and soldered in a push type Christmas lamp socket. I tried several blinkers 2.5 V 3.5 V 6 V and 12Volt blinkers. All available at Walmrt for about $1.25 a pack. The packsare marked replacement and say nothing about flashers but the first two in every pack are the blinker lamps. (from

the left) I installed on in the longfellow and instantly i had the rig keying nicely n a more or less steady rhythm. I bricked the Key for this. Then i thought most of my rig are cathode keyed so I installed the lamp across the key (old indicator lamp reinstalled.) It worked very well. As long as tests are as short in duration as practical itis like have an extra person around to help.

Back in the mid 60’s I designed myself an auto CW ID unit. It used logic flip flops out of which I made a shift register and then gates to decode my call from the registers outputs. Speed could be varied by varying the clock rate to the register. 73 – Mike

Yes I am very concious of the time when I do it. I thought about a notched wheel and micro switch or photo cell.
And that would be very easy to do. In the meantime this allows me few minutes of test time which is all I really need. I have a Kantronics set up I used what seems like a hundred years ago for Morse and RTtY. I have it all but it is for my Vic 20 which I still have but the vic 20 has a PSU problem. I bought the Kantronics at the Ham store at the Rome / Utica NY Airport many many years ago. However no Computer allowed in Sudio B. Only wood tubes and me. I even dont like taking in a digital voltmeter

FB Don,

After I made that post I started thinking of how a contraption using electro-mechanical devices could be used to send an automatic CW ID loop that would be ancient-technology compliant along the lines of your notched-wheel-and-switch. I hadn't thought of a photocell, though - good idea.

During my research into spy type low tube count transmitters I was directed to the Flyling Doctor radio story in Aus. That young fellow developed a small typewrtier that sent morse code when you typed normal. So simple one with patience could actually build one today. Totally electromechanical (about 95% mechanical) and I am betting fool proof. If I was younger and had more time I would perhaps make the key and notched device for one letter each week or so and eventually I would have one. Just to send a single repeated message like VVV DE VE3LYX would be much easier as you already indicated. That I may try. Got one more longfellow to finish first (20M VFO)

I found a small photocell in my junkbox and made a paper disc and punched out my Id with a paper punch. it worked. The Photocell is really too small but the concept works. Wheel should be about 10 to 12 inches. to give the right spacing. Ambient room light is enough to trigger it. Itisa project for some other day but the idea works.

Here we go again! The auctioneer is ready, the tent (heated) has been rented, the caterer booked, and the catalogs printed, in the mail and on the website.

The second live auction, also with internet, telephone, and absentee bidding, will be held on Sunday, November 13, 2016 at 11:00am in Carlisle, MA. (Details at <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwrwhr1hsex2PostEiPrnvA7QHOHCNxQDzmP1-Ydf4H2oPEX1sE5WZPPDTtxIqk80AsdBnR2JhutaImRjFKjNz7eJTjqhdTXNCvXVYMSUgg1foDjL0hvkmqt8pWH9t_jTMQ==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==> www.terreyauction.com.) And, again, there will be a BBQ (6:00pm to 9:00pm) and Preview (noon to 10:00pm) on Saturday.

The Internet Bidding Website is up and running at: <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwmOqp_jU3ukUTmEbJ-7vKfmlLhxnNxKRtYfOvAhhPZijX61Ih7N2rbUQb8CcIYtauyuFV4dOH47l-VVu0iXUmQ-jeBVdc2XhTKA3yeeQBcXQPp_o3W4n-KjINe6i8vE60F5lJ1fiyL8Asbkb_D5Tp2C43lEnbWgyWK-rgzxqvkQ9b0n_RUQRG4d_lZjKn7_Idw==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==> Proxibid Terrey Auction Website.

It looks like it will be a repeat of September...great items to bid on, lots of collectors attending, good food, all in a heated tent. As I said in September, if you attend, you probably will meet collectors that you have known only via eBay or only heard about. (Take a look - <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwmOqp_jU3ukUyJOo0ekX2wxkv8_BmduVIlXBWhh_Le-d17OkkLtIkzob9ByLJIUlUnFfEgoTb84uDXhNnkW5YA7rgsM2aIvu-hyhgbkUn27p6v1XZtJd9t-rmW64Us-DYdFfbgyvHY_s4Ra-yIKjRLgkVVfvVxHGbWwzd1w_1btXs9bdIOWjmt7TCGSGcbVjEA==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==> Session #1 Photo Slide Show).

A few comments from the attendees: "I want to thank you for having the auction. It was interesting, exciting, and conducted very professionally and with class." "I thought it was one of the best run auctions I have ever attended, and I have attended many." "Wow!"'

Please respond on the website to let us know if you "plan to or might attend" the auction, preview and/or BBQ, so we can plan for all.

AT AUCTION...will be over 300 vintage radio items including sets from Grebe, DeForest, Federal, Jones, Kennedy, Kodel, Chelsea, Crosley, Miraco, Radio Shop, SE-SA-DE, General Apparatus, Sleeper, Western Coil, others, plus early wireless items. Many sets have rarely been seen at auction.

ABOUT THE PREVIEW PARTY <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwrwhr1hsex2PostEiPrnvA7QHOHCNxQDzmP1-Ydf4H2oPEX1sE5WZPPDTtxIqk80AsdBnR2JhutaImRjFKjNz7eJTjqhdTXNCvXVYMSUgg1foDjL0hvkmqt8pWH9t_jTMQ==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==> <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwrwhr1hsex2PostEiPrnvA7QHOHCNxQDzmP1-Ydf4H2oPEX1sE5WZPPDTtxIqk80AsdBnR2JhutaImRjFKjNz7eJTjqhdTXNCvXVYMSUgg1foDjL0hvkmqt8pWH9t_jTMQ==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==> <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwrwhr1hsex2PostEiPrnvA7QHOHCNxQDzmP1-Ydf4H2oPEX1sE5WZPPDTtxIqk80AsdBnR2JhutaImRjFKjNz7eJTjqhdTXNCvXVYMSUgg1foDjL0hvkmqt8pWH9t_jTMQ==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==>

Saturday, November 12, 6-9pm

The caterer, "Lester's Roadside BBQ," is

all set: Texas Sliced BeefBrisket, North

Carolina Pulled Pork, Pulled Chicken,

Coleslaw, Rice & Pinto Beans, Collards,

plus liquid refreshment!

Lester says, "There's only one way to

cook real Southern Barbecue...Low and

Slow. Slow cooking at low temperatures

for long periods of time keeps the meat

moist, tender and full of natural flavor."

Am I trying to entice you to come? YES!

A printed catalog is available...just request one on the website.

Detailed directions are on the website.

If you wish to leave an absentee bid, or bid by telephone, contact the auctioneer,

Wayne Tuiskula (MA License #2591)

www.centralmassauctions.com <http://r20.rs6.net/tn.jsp?f=001FhCx9Rj2N0sOq0QqPazQpGS8MK39qHXRqzm3fvFxc9PAx2_NLMRUwmOqp_jU3ukUJj1w1SE0kfelCUtC6TNF0aa5HVO2kSTYB00vZBy-BsbHbJsxoW96a5VMVe4uhl_y-p0YfrT9iwYWrhyGuhbIOtboftg3v79pYY6K87Y_X8cQjqvvV4dGqg==&c=FQVWLTnDNd_OxLBM2p_ie8gvay-EB4aE587xHXHmaBUNZmSk_Zn3ag==&ch=KdcwmGh-_VQfpEVNCBWlJsrXEZVKWiev6_PIesEDoYfcr1IzKZqbVA==>

Indeed, some are very nice. The first picture is an American Marconi Magnetic detector from about 1912. Not interested here as I have the original UK version. The second picture is a collection of coherers. I am interested in the top one which is French, the others are EI and common. The third photo is a Grebe CR-18 special which I have. And, the last is a homebrew spark TX, not much of a big deal in my opinion. Of course there are 300 lots and this is just a few of them. 73 – Mike

I have this NOS 4B39 4 pin rectifier by Lewis & Kaufman.
Cannot find any information on Frank's.
Need fil, piv and currents.
Maybe trade with a needy collector would be nice too?
Regards,
bob...w2ami x wn2ami 1962

This Longfellow thing maybe got out of hand. The first worked so well I built the Pigmy and it is up and running on 80M. But all along I was working on a VFO controlled one for 20M. The P is triode connected and GG but easily reverseable of need be. That basic idea came from appor man's linear in the early 40s (QST) that used four 6l6 tubes in that manner. On this rig I used a voltage doubler to push the 25L6 tubes a lot harder. Today I finished the tank circuit and checked it on the GDO. tunes above and below the 20m band and is shunt fed. VFO is slug tuned. I have been pokng away on this one doing only a bit at a time. Soon there will nothing left to do and it will be put up or shut up time. This one is a colpitts and I have not done much with that circuit ever so I am hoping I figured it right.

14315. Upcoming 630m Crossband Night - Saturday, Nov 12th

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-06 04:01:12 UTC
From: Steve
Topic: 14314 Message: 14315

I know there are several folks on this list that are interested in 630m band actvities. Some of you may even be planning to get on 630 when it becomes a ham band in the U.S. Here in Canada, we've had the band for a couple of years now and regular 'crossband' QSO events have allowed interested amateurs in North America to explore the band's potential by working the 630m Canadians.

The next 'crossband evening' will be one week from tonight, on Saturday, November 12th.

As in previous events, the participating Canadian CW stations will be calling CQ on specific allocated frequencies and will be listening on their announced HF (QSX) frequencies, within the 160, 80 and 40m bands.
In past crossband nights, transcontinental CW QSO's have been completed as have contacts between the west coast and Hawaii.

The popularity of this event has continued to increase each year as more and more amateurs become interested in this part of the spectrum (472 - 479 kHz). Hopefully this trend will continue next weekend and that you will consider taking part in the one night event.

As in the past, numerous U.S. 'experimental' stations will be active on the band, either running CW beacons or seeking two-way QSO's with other stations in the experimental service. As well, some may be operating WSPR or JT9 modes. All are interested in your reception reports and most of the experimental callsigns can be found via a QRZ.com lookup.

The Maritime Radio Historical Society are also promising activity, as KSM / KPH in Bolinas, California will be activated for the night, sending weather notices, press bulletins and possibly engaging in two-way work with historical naval ships involved with the MHRS.

All told, there will be six different participating Canadian stations that will cover most regions of the continent, should propagation co-operate!

More information as well as a detailed schedule of times and frequencies may be found here:

http://ve7sl.blogspot.ca/2016/10/novembers-630m-activity-cw-crossband.html

As well, if you have not participated previously, you will find some useful hints to help you out.

Details were previously released on both the ARRL and RAC 'news' pages, here:

http://www.arrl.org/news/630-meter-special-event-set-for-mid-november

and here:

http://wp.rac.ca/

I will also post a reminder next Friday, one day before the event. I would also ask and encourage you to pass this information forward within your blogs / Facebook / Twitter pages as well so that as many amateurs as possible are aware of the activity. Please e-mail me if you have any questions and we all hope to see as many participants as possible next Saturday night!

73,

Steve / VE7SL

Back in '65, in my first quarter at college while living in a dorm, I built a solid state transceiver. I believe it covered 80, 40 and 20 CW and probably did not put out more than about 10 watts. The pair of output transistors were expensive Germanium TO-3 types and did last for a short while. I did make numerous CW QSO's with it running a piece of wire out of my dorm window. The good old days. - 73 - Mike

Speaking of VLF I have been playing with this for a couple of years as it doeas a lot more then just SAQ . . Two diodes and a wire antenna and you computers sound card. Great for an intro to VLF and various versions available.

Unlike my VLF regen it is not bothered by the local AM radio station.

Yep! I've got it on several of my machines and have played with it.
Never tried to receive SAQ with it, though - no gumption to get up early
enough to catch SAQ (although my usual time to get up is 0530 local, any
earlier is a real chore).

Hello all. Just joined the group so would like to introduce myself. Have have be a ham for about 25 years getting my license later in life than most but from the time I saw my first crystal set as a child have been fascinated with radio. I love building so seem to end up doing that more that I get on the air. I am working on correcting that but it's not easy! I was reading the NAQCC November newsletter the other day and an article by NW2K about the Bruce Kelly QSO Party caught my eye and I thought, Wow that sounds like fun. So here I go again. This group was also mentioned in the article which lead to my asking to join, thanks for having me. NW2K e-mailed me some info on building a 1929 style Hartley transmitter as well as a power supply. The transmitter is for the 80 meter band and uses a type 27 tube. Don't really have an antenna for 80 so would like to build it for 40. Will that tube allow me to do that or would another type be a better choice? Whatever type I use it will need to be ordered as no swap meets between now and December. Any recommendations for where to purchase?

I have had a few older rigs over the years, an ART-13 and Heathkit Apache. Currently I have an Eico 751 that I would like to get working and on the air. Picked it up at a swap meet years ago for my son to use while learning CW. It had quite a bit of VFO drift at the time but has not been powered up for 10 to 15 years so may have other problem now as well. If I remember right the VFO is solid state with just about everything else being tubes. Need to get it out of the shed and check it out.

Well that's probably more than you ever wanted to know about me. Thanks for reading and I look forward to being a part of the group.

The Pigmy longfellow has been in QSO and getting decent signal reports. The rest of the tubes finally came (yesterday)and I had to retune the final tank due to the additional tube capacity. After a few adjustments I warmed it up and called CQ. immediate answer. VE3DCX again. This is not the first time he has replied to a new rig. It uses the tiny crystals and I have only a 3579.5 and a 3575.5 so i need to find some more.
The other 20M longfellow project does not appear to be my best idea so I am redoing it as a five 6l6EH GG AMP like the 1940 QST article.
Anyway I will be active with these two rascals for a bit.
Maybe we need a longfellow event since several of you have versions built.

Me too. I learned to solder at age 6 or 7, and was building working regenerative receivers (but not good ones) when I was 9 or 10. I built my first working superhets in high school. I'm taking from spare parts, not from kits.

> I love building so seem to end up doing
> that more that I get on the air.
>
That describes me as well. I still manage to get on the air several times a week, though.

A 27 will oscillate on 40M; no problem. You'll be doing well to get a watt of RF to the antenna, but you'll make contacts.

> Whatever type I
> use it will need to be ordered as no swap meets between now and
> December. Any recommendations for where to purchase?

Try http://www.esrcvacuumtubes.com/
I've bought tubes from them before and have always been a happy customer. I just look on their price list and it says an ST '27 will cost you $10 and a globe-style runs $14. No connection with ESRC and other disclaimers apply ;-)

James,

First off, welcome to the group.

The Eico 751 is the power supply for the Eico 753 tri-band transceiver. I still have a 753 that I put on the air, mobile, back in the 1970's. It has the solid-state vfo, and yes it was rather drifty especially when I was running the heater in the car. It's not the best of rigs, you might be better off to put your effort into something a bit better like a Heath HW-100, HW-101, or SB-100. If you would like my 753 for spare parts I'd be happy to send it to you if you pay for the shipping.

73,

Jim Hanlon, W8KGI

I have a Velvet vernier that isn't quite as "velvet" as it should be. I'd like to try getting a little lubrication in there to see if it smooths out a little, but I wonder if anyone has some advice about the best way to do this?
This is the old Type-A that one found int the National Browning Drake "Regenaformer" kits along with the DX capacitors in the mid 20's.
Thanks!
Andy K0SM/2

You are correct, it is a 753. I grabbed the manual off the shelf to include the model number in my post and didn't notice that I had the power supply book in place of the transceiver. I was thinking it would be interesting to see if I could connect a DDS VFO to eliminate the drift but haven't gotten to it yet. Maybe that was why they were almost giving it away at the swap meet! Let me get back to you about shipping the parts unit. It is very tempting as I believe my unit is missing some of the shielding inside.

Thank you and 73,

James/KB7LJP

I want to comment on the color....I have the same model from about 1940 (see https://www.prismnet.com/~nielw/shack_tours/wa5vlz_jan88.htm) and the color surprised me. I expect everything from that era to be black but that model of MSS is light brown. I've always wondered about it but from inspection it looked original. Good to see confirmation.

My photo is from my AWA 1988 Linc Cundall effort. On 80 and 40 the MMS doubles in the final, fortunately the 1/2 "harmonic" of the AWA contest frequencies fall in the 160 and 80 mtr bands. I need to blow out the dust, add a little more output filtering and try it out again in January LC.

With mine if the QSO is short you hardly notice the drift but Meissner offered an external "Signal Spotter" crystal adapter. Are any of these out there looking for a new home?

14342. Upcoming 630m Crossband Night - Saturday, Nov 12th

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-11 17:34:58 UTC
From: Steve
Topic: 14314 Message: 14342

This is a reminder of tomorrow's '630m activity night'. Highlights of the evening will see six different Canadian stations seeking contacts with other amateurs in North America via the 'crossband mode' as they call CQ on 630m CW but listen for replies on their announced (QSX) HF frequency. As well, there will be an increased level of on-air activity from many of the U.S. experimental stations, as they beacon or work each other on various modes including CW and JT9, the WSPR QSO-mode. The experimental stations are also seeking your reception reports.

More information may be found here regarding the activity night, including a detailed list of participating Canadians along with their respective transmitting and QSX HF listening frequencies.

http://ve7sl.blogspot.ca/2016/10/novembers-630m-activity-cw-crossband.html

As is often the case, old 'Sol is threatening to throw some junk our way over the next day or two, right on time for our event but please don't let that stop you from participating as often this can actually enhance propagation, especially on the north-south path.

We hope to see many of you tomorrow night!

Worked VO1NA and VE3OT cross-band 630m/80m. VO1NA peaked 579, VE3OT 589. Could not hear any VE7's before my body gave up and I had to quit.

Heard several of the US experimental stations. Best distance WG2XIQ peaking 549 at 1725 miles. Best signal WD2XSH/46, 599+10 at 609 miles.

Rx antenna: Beverages ranging in length from 550 to 700 feet.

Posted recordings of VO1NA,. VE3OT, WG2XIQ to AudioBoom. A search for my callsign there should find them (I think).

MY HB LF receiver only goes to 450+. I can change it to probably around 480 easily and recalibrte the dial. I also used the beverage ant as it likes it a whole lot better. (No broadcast interference) My regen has a pair of 6v6 tubes. I am leaving the 6v6 audio amp but going to a conventional dual triode ahead of it. Probably a 6sl7. This sethashad so many mods it aint pretty. However tis interesting.

14349. 1942 Collins HF station. + 01a BK Hartley project

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-15 11:02:02 UTC
From: dulmagedon@...
Topic: 14349 Message: 14349

While my focus at the moment is being sure I am ready for the BK I managed to score a Collins Hf station . The RX is at the post office today and the TX is enroute to my sisters in NYS. I should be good on 160M 80M and 40m plus the in betweeners should I be able to get them running.
I bought them in memory of my Dad who was in the 50s and 60s a radio design engineer for Collins Radio (Canadian Division) Since he also was Chief eng for PYE Canada I have that covered with my No 19 WS set.

He was thrilled when I bought it even though he was then 90 years old. I remember him saying in his hoarse voice, "now you finally have a real radio". I think he would approve of the TCS station.

I built another BK rig and have been rubbing on it here and there in the last week or so. Not totally happy with how it sounds. Have tried several things but haven't found the "magic screw" yet. it is useable but I hope to improve it some. I have played with Grid leak values both C and R . Different coil taps . Split or direct cathode connection. I might just be too close to the montor RX but I hope to improve it. Time is closing in. It is a 40M rig. 01A. It looks good which worries me.

Sorting thru the TCS rx today. Have most of it figured out I think. I see a separate screens pin. Reminds me of sorting hru my ARC5 stuff. ONe bum tube found (open heater) and a bad power switch which doesn't actually handle anything inside the radio anyway but I replaced it anyway. Now all I need is a PT boat to go with it!

Larry -

Yes, it is a relay. The coherer, even in the low resistance state when RF is present still cannot handle much current, so, a high resistance relay is used with it. The relay then in turn rings the bell and at the same time decohers the coherer. Later, more sophisticated coherer receivers would also have RF chokes in them as the spark created within the bell was enough at times to coher the coherer. 73 - Mike

Hi, new guy here. Have been gathering parts to build a rig for the BK QSO Party using information from VE7LS's site about a TNT Hartley. He wound his own RFC but to save time now I would like to use something I already have and wind my own later. I have attached a picture of some options I have, does it look like anything here would work? Item 'D' is a 250MH but also have them in 800MH. Item 'C' is not labeled but is a coil wound on some type of core and glued inside a cardboard tube. Cant tell if the core is plastic or some other type of material but is not adjustable.

I received the parts for a modern power supply (solid state) and found one of the filter caps had a nice dent in the side of it. Looks like the power transformer mounting ear gave it a good wack during transit. Is it safe to use or should I ask for a replacement?

Lots of other questions but to keep this from becoming a book will ask them later.

Thank you for any help you can give.

73,

James/KB7LJP

James - I'm not sure what you are using to measure your RF chokes but it looks like it may be out by a factor of '100'.

RFC A and D are 2.5mH chokes so I imagine that your '800mH' choke is probably an 8.0mH.

When I made the homebrew chokes for the TNT and other rigs, I was surprised at how low they measured...just a few 100uH. It seems that not a lot of choking is needed in many of these circuits!

You can use the 2.5mH chokes with no problems at all and if you need to wind one on wood, they will also work just fine.

Good luck with your project and I'm looking forward to having some more 'west coast' company in the BK next month.

I have attached a picture of some options I have, does it look like anything here would work? Item 'D' is a 250MH but also have them in 800MH. Item 'C' is not labeled but is a coil wound on some type of core and glued inside a cardboard tube. Cant tell if the core is plastic or some other type of material but is not adjustable.

I received the parts for a modern power supply (solid state) and found one of the filter caps had a nice dent in the side of it. Looks like the power transformer mounting ear gave it a good wack during transit. Is it safe to use or should I ask for a replacement?

Lots of other questions but to keep this from becoming a book will ask them later.

Thank you for any help you can give.

73,

James/KB7LJP

I ran across one source (either Grammer or Terman, I think?) suggesting that the plate choke only need be about ten times the inductance of the tank coil. To be even more effective, the supply side of the plate choke should be bypassed with .001 - .02 uF, although we do not see this bypassing often on the earlier circuits.

Helpful. Tks Steve.

To be even more effective, the supply side of the plate choke should be bypassed with .001 - .02 uF.....
I did this with the cap cold side going to an earth ground. Had no effect on the signal tone quality or any other aspect.
Of course, that was but one instance.

I wonder when this became popular? When building my Tri-Tet single 6L6 oscillator using a 40m crystal, I was only interested in 10m output. The Handbook circuit I was following was from 1934 and it was a 80/40m tri-tet circuit. There was no bypass at this point but when adding one, my 10m output jumped from ~ 2 W to 4.5 watts... a very worthwhile improvement.

Hi James, and welcome!

I see you've received some answers on the RFC question, which which I concur, but no one answered your question about the banged-up electrolytic capacitor.

If it has a dent in it I wouldn't trust it. Electrolytics rely on on a very thin electrolytically-grown (go figure!) dielectric film, and as I see it it could be easily compromised due to mechanical damage. I'd ask for a replacement.

I bought this ol blister from Florida as part of my Collins project in Dad's memory. This one was in tough shape ad not Collins factory built although definately their design.. More then once I wondered if I had done something stupid. Cut wires, burnt parts, 2 bum tubes were slowly fixed and unhooked wires were reattached hoping it was the right spot. Finally yesterday afternoon it coughed to life. Little by little I have been getting it a bit better. Now it is usable although the BFO is not working. I chased the circuit for continuity and that was OK. Still works well on AM and I spent the evening listening to some 160M stuff. It is very low noise compared to my other rxs. I am taking a break now as I am expecting the TX a Collins built TCS 12 to arrive this week. I sure hope it is in better shape then this one was. I have to go to my sister's to get it. I feel a visit to Cracker Barrel coming!

Meanwhile I am working on my last BK build. It works but is raspy. I haven't figured it out yet so was watching the bypass the RFC thread with interest.

Thanks for the information. I have not tried to measure them yet but think I could do that with my MFJ -259B. Just grabbed some chokes from the junk box to see if anything I had might work. Item D is labeled Aladdin, 64-256-1, 250MH 20%, 512-026559, 6211. I will give A or E a try for now to get things working then wind my own later. I have sure enjoyed you web site!

James –

I do not believe that the MFJ-259B is capable of measuring inductors in the mH range. It may be capable to measure up to around a 100 uH. 73 – Mike .

RFC A and D are 2.5mH chokes so I imagine that your '800mH' choke is probably an 8.0mH.

When I made the homebrew chokes for the TNT and other rigs, I was surprised at how low they measured...just a few 100uH. It seems that not a lot of choking is needed in many of these circuits!

You can use the 2.5mH chokes with no problems at all and if you need to wind one on wood, they will also work just fine.

Good luck with your project and I'm looking forward to having some more 'west coast' company in the BK next month.

So in light of this discussion I had a "what if" moment and drug out my last hartley I referred to earlier. I rewound the RFC more like I would use on a larger transmittter raising the turns count substantially . I reinstalled it a guess what.? Cured. Wind as many turns as you think will work then double it That is my new advice. I am on 3602 if anyone feels lucky.

Speaking of RFCs......

The homebrew solenoid RFC in the plate tank of my 203A 160M MOPA caught fire a couple weeks back. Luckily, it extinguished when no further RF was produced. The fuel was polyurethane. Not really considering the potential future problem, I smeared the stuff over the entire RFC including the end terminals when I probably should have only coated the windings.

I switched it around assuming the "cold" end would be under no RF stress. That worked for a while, but last night while in a QSO with a VE6, it lit up again at the same spot which is at the "cold" end. I guess it is resonant where it shouldn't be, perhaps at a harmonic. It is wound on a 1/2 in. dowel in three sections, approx 800uH if I remember correctly, so plenty of reactance at 160M (tank coil is around 80-100uH).

The cold end is bypassed w/ .004uF mica. Another indication that there is RF bleeding through is when B+ is turned off, 203A cathode grounded (via center tap), and 866 filaments lit, the mercury vapor rectifiers dimly light up when the preceding stages are keyed.

Probably going to rewind a new one with more care in applying the lacquer and more rigorous testing to ensure no harmonic resonances.

Strange that the one installed worked for a long time. This failure seems to coincide with a 203A tube swap... not sure exactly how that might factor in to it or just coincidence.

Interesting, Eric.

Years ago I grabbed an old burned open 300 watt vitreous wirewound resistor to use as a form for a choke in a high power HF amplifier. I was able to get all the resistance wire and outer coating off so I had a nice clean white ceramic form to wind a choke on. Well it was clean on the outside. Inside it was painted or coated with some blue substance. I didn't think that would hurt anything.

The amp acted strange and when I investigated I found that as soon as I hit it with RF the inside of that form the choke was wound on lit up bright enough to make my eyelids snap shut! What I observed in that brief instant reminded me more of super bright corona than an arc. With considerable time spent I was able to clean out the internal coating. The choke worked OK after that.

More recently I blew up a choke that had a series resonance too close to a ham band. It had worked for a while but I knew the amp wasn't loading quite right on that band and that the choke was responsible. My mistake was assuming that what worked OK for a while would keep working OK.

These things get interesting when you get to higher power levels!

The most trouble I ever had was when I made the RFC for my twin 811A linear. The trouble is as much as a pain these problems can be it is also when I learn the most.
When I built the Weskit style transceiver I used a single HD hb RFC from the transmitter for the Regen as well since it was right there. That regen works very well and now I wonder if that is partly why.
Anyway the new hartley is ready and waiting.

14379. Gas demonstration in old tubes

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-23 19:11:38 UTC
From: aflowers@frontiernet.net
Topic: 14379 Message: 14379

A while back I tested an old 211 on the AWA's big-bottle tester at the museum. It had a nice pink glow with about 500V on the plate, and I understand this is pretty common with the old metal-plate transmitting tubes due to outgassing of all that scaffolding over the years. It looked pretty cool and might make for a nice physics demonstration.
So I have a physics question before I try this in my basement: do I need to apply filament voltage see the ionized gas, or can I just and look for the pink haze by bringing up the plate voltage only? I would think that the gas would ionize regardless of the filament being lit and might be easier to see in tubes with bright filaments if lit, but maybe you do need to accelerate some of those free electrons to get aurora-in-a-bottle. I was thinking I could essentially tie the grid and plate together like a simply emission tester, but just not apply the filament. These would be thoriated tungsten or pure tungsten elements, so I'm not too worried about stripping any coatings by running the plate with low- or no filament current.
Thanks,
Andy K0SM/2

Topic: 14379 Message: 14380

Andy, I think you should light the filament to get some free electrons floating around to enhance the probability of an ionizing collision, which is necessary to "strike" the plasma. Otherwise, you may need to apply such a high voltage to ignite a plasma that it could damage the filament, grid, or plate structures. (Ask yourself why a mercury vapor rectifier would need a filament.)

In another life I had been a process engineer for several plasma processes.

Mike, Joe
I recently purchased a pair of SUPER WASP receivers from John. One is complete and the other was incomplete. I understand the Wasps were basically a kit since the Pilot Company was mainly a parts supplier to the builders at the time. Hope to get the completed one working son.
I bought what was advertised as a "Wasp" off of ebay but when I got it it was not a Wasp. There was a hand drawn schematic inside with scribble on it mentioning the "wasp" radio but it seems whom ever built it did not use the schematic at all.
John is a real nice guy and I love the radio. It should go well with my breadboard transmitter

14389. Interesting find

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-28 19:50:31 UTC
From: K3PID
Topic: 14389 Message: 14389

I was looking over (and thru) an S-39 that I purchased at an auction and I came across a 5 page instruction set plus schematic and pictorial wiring diagram for a Philmore 1 tube code oscillator kit model CO-206. The schematic and the wiring diagram are both “approved” by R Burke, 5-5-55. It uses a 12AX7 or 12AT7 with half wired as the rectifier and the other half as the oscillator. The schematic shows a three wire resistance power cord but the wiring diagram shows a two wire cord with a 350 Ohm resistor for the filament. The instructions give the option of using a 10,000 Ohm potentiometer in the cathode keying circuit to provide a variable tone... Maybe this winter when the snow is real deep and the BK is over, I might build it for fun...

14390. Hartley Pwr Supply

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-11-29 03:56:27 UTC
From: James Sweeden
Topic: 14390 Message: 14390
Attachments: 1 described; binary payloads are missing from this source WARC

Hello all. I put together a power supply for a TNT Hartley using a 71A and have attached a picture as I am looking for feedback concerning safety. As you see it is constructed on a piece of plywood but plan to put it into an enclosure once it has been tested and no further modifications are needed. It uses a LR8N3 3-terminal regulator with a TIP50 as a pass transistor. I placed a 3.5K pot in series with one of the resistors to make the B+ adjustable (100VDC - 250VDC) and mounted it to the front panel but am wondering if that is a safe way to to that Am I risking placing HV on the front panel should a part fail? I have connected the panel to earth ground so am thinking the fuse would blow should that happen but thought I would ask to see what you think. Also wanted to know if I should also connect the ground plane of the HV board to earth ground as well.

Thanks for your input, 73

James/KB7LJP

James, nice job on the power supply. Fall must be power supply time. I've recently pulled an old PS project of mine off the shelf to complete....see
http://w0vlz.blogspot.com/search/label/Power%20Supply
http://w0vlz.blogspot.com/search/label/Power%20Supply .

Three things you may have already thought of that I do -

- Insure that your fuse is connected in the hot side of the AC line

- Ground everything that may be exposed. Normally this is taken care of by the metal chassis but you and I are using a wood chassis so separate ground lines to transformer shells and PC board ground planes are needed.

- If your transmitter does not require floating B- connect it also to AC earth ground.

btw, what are you using for a B+ transformer? Sources for HV parts are getting harder to find.

73,
Niel - W0VLZ

Hi James. I'm using the same regulator and pass transistor setup in a power supply here. According to a Texas Instr. data sheet the failure mode on the regulator is typically a short or open on the in/out terminals. They mention nothing about the ADJ pin in failure mode. My hunch is you are unlikely to see any HV on the ADJ leg or on the adjustment pot. If your pot is at the ground end and the panel also grounded, you are likely safe. Your fused primary helps too. Like you, I'm interested in other opinions here.

Joe, the original poster and builder of the supply (James/KB7LJP) said the Hartley used a 71A, which has a 5V filament, and that the supply is adjustable from 100 - 250V.

Missed you on the AWA topband net last night. We had a good group.

Hello Larry,
? ? ? ? ? ? ? ? ? I appreciate you bringing me up to speed on the power supply. From the looks of the "iron" on it I thought it might be a little lacking in voltages, and what you told me explains everything. I thought the pot on the front panel was probably there to adjust the A or B voltage.?

I did plan on joining the AWA ";Topband" Net last night, except my wife had what we call a "sugar crash". and I had to keep an eye on her. With a little orange juice and some sugar pills ingested all was well. She is a "hypoglycemic" and occasionally her blood sugar levels plummet to an unacceptable level. Unfortunately for the both of us at around 8PM last night she had one of her occurrences. Fortunately all was well afterwards.?

I do hope to be on the Net again in the near future. I'm glad a good time was had by all in attendance!

14401. BK Preps

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-01 11:58:30 UTC
From: dulmagedon@...
Topic: 14401 Message: 14401

Been busy getting ready for the BK.
I reworked the last Hartley (01a)to my satisfaction. I did a hard rub on the regen I built with the 26 tubes during a demo and got it from the "it works" level to "it performs" and plan to use it a bit on 40M. Bought new batteries for it. Took the Dreipunkt German design(basically a Hartley) tx and gave it a good going over and a few minor modes. It has a special sound . I call it German CW. You'll hear it right away. Very distinct. It is on 80M in the 3500 to 3600s. I checked out the rat trap Hartley .Still works great so it is ready to go. Then I took my original 40m TNT which now sports a 10 tube and did a hard rub on it. I repositioned its riginal antenna coil for better coupling. Not too close to pull but close enough for good power. I was surprised I still had it as I had been using a cap take off on the coil. I also did a bit of by-passing which seemed to improve it noticebly. I hooked it to my ancient telegraph relay and hooked my hacksaw hb bug (dah completing) to it. many moons ago when I was first hm I had a heathkit electronic keyer (and still do) that I taught myself to use with my left hand. I figured I was too old for that now and so since getting back on CW the last few years I haven't tried it but this week while fooling around I tried doing it on the hb bug. Much to my surprise I can still do it. Now the hb bug is not for speed. It is just easier to use as it auto completes the dahs. It will have a distinct sound as I intened to use it on the TNT. And I will be sending left handed. (I believe non electronic bugs(ie viproplex etc) are allowed unless that rule has been changed.) I look forward to the event. 80M BTW has been open early mornings all week. And I do mean "OPEN!" not just open.

Don, I am not aware of any restrictions on the type of key one can use in the BK or any other AWA CW contest. AFAIK you could use a solid-state electronic keyer or even a CW keyboard, but both of those would be silly for the BK.

Starting this year I either use an iambic keyer or I don't operate.
If I learned anything last year while sadly under-performing as
W2ICE/1 and while recovering afterward it was that my days of using
a straight key are over. After several injuries and surgery, the arm
just isn't what it used to be.

14411. No Restrictions on Keying

Yahoo group: AWAGroup (2014 — 2016)

From: Whitebear1122
Topic: 14401 Message: 14411

There are no 1929 BK keying restrictions what-so-ever. You can use a key or a bug or even a car horn button :) It doesn’t matter which one you use, just be there with it :)

And I want to remind Paul since he seemed to have forgotten, that he did a FABULOUS job last year as W2ICE/1 and over-performed. Thanks again Paul for doing that last winter. Next week Bill K4JYS will be flooding the airwaves as W2ICE/4.

73, Scott WA9WFA

Have to go to Watertown in the morning and meet my sister. She has the other half of my Collins TCS station.
Guy wouldn't deal with a Canadian but sis' came thru for me. It is supposed to have a PSU with it. Here is hoping it is operational or close. TCS 12 tx. I know it has a non stock milliamp meter (lower). I hope it is a standard size as I have several. I have the RX up and running already. It came from Florida direct by mail with no issues. Also killed my chair yesterday while reorganizing my bench. Not the first chair I have killed BTW. XYL heard the crash and paniced a bit. Was kind of a "whale on the beach" moment as I tried to free myself from the chair and find a way to get up again. Tis the only chair I have had in my shack since the 1980s.

14417. National SW-3 Help

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-03 14:10:46 UTC
From: Tim Haake
Topic: 14417 Message: 14417

In the past year I have bought a few of the little National black boxes. The first was an SW-3, then a SRR, and then a 1-10.I decided to get he SW-3 out and get it working and immediately became confused with what I have. The set came with a lot of spares, a set of coils in boxes marked SW-5, and spare tubes type, 56, 27, and 58. I also got a number of copies of information from old QSTs and a SW-3 manual manual from Vintage Manuals.
First off I am confused with the set in that the info from QST and Vintage Manuals shows a front of the receiver with a control under the main tuning knob which is a side turning type thumb control and my receiver does not have one. Second my receiver has a total of 4 places to plug things into inside the chassis. Two of them are standard 5-pin tube sockets and two of them are glass ceramic mounted above the chassis sheet metal. The schematic shows three tubes and TWO coils in all the circuit diagrams I have yet I do not have that many places in the set. Where am I going wrong with this set?
Secondly the QST data info comments on running this set on 135+ to +180 volts DC and the appropriate power as required for the choice of tubes since the set could be had in several filament flavors. I also came up with a model National model 5880-AB "dog house" power supply that puts out 2.5 volts filament and 300 volts DC.
Can an SW-3 owners hep me out?
Thanks TIMWA0TSY

Tim,

If you don't have the RF gain control under the tuning knob and only two tube sockets you may have something that's not an SW3. Post some photos so that we can take a look.

Niel,
OK, MY STUPID! I pulled off the shelf the SRR receiver and not the SW-3 ! They both look quite similar but two different receivers inside. OK so with that resolved what do I do about the B+ issue? As I said earlier the dog house I have puts out 300V and it is marked clearly as being a 5880-AB which I am lead to believe that is the correct power supply. The tubes in the dog house are a pair of type 58's and one 56 which are 2.5 volt filaments so that matches that much of the 5880-AB supply. I am concerned about the much higher B+ of 300 volts.

Tim,

Check your power supply to see if the parts are original. The transformer and choke are potted together. If the guts have been changed out someone may have taken some liberties with component values

The original National power supplies were rated for a 110V line. You're probably running 10% higher. I have a good sized 12 V filament transformer under the desk connected as an auto-transformer to get my station line voltage down to around 110.

You need to check the PS voltage under load. I believe the load/bleeder resistor is in the SW-3 so the voltage you see is the peak charge on the filter caps. Voltage under load should be quite a bit lower.

Inside the SW3 is a multitap load/dropping resistor that splits out the various voltages required. If that resistor is bad you'll have voltage problems also.

Which coils do you have with your SW3? See https://www.prismnet.com/~nielw/sw3coils.htm https://www.prismnet.com/~nielw/sw3coils.htm Do your coils match the tube lineup?

Hope this all helps.

Howdy Tim, This may help you out on the ID; The side-moving dial below the main tuning control, is the gain controlfor a SW-3. Further, the 2 sockets mounted on "stilts" will be an odd 6-pin configuration and they are forcoils for the RF and detector. Why the odd 6-pin socket has several stories. The spacing normally doesnot match the standard 6-pin spacing (unless of course someone changed them).

There are 3 distinct models of the SW-3. I believe the National 1-10 was a VHF/UHF (in the day) RXwhich covered approximately 1 through 10 Meters (not metres).

Please feel free to email with any other questions. BTW: Do you have coils for an SW-3? I may havesome spares.

Thanks Roger for the iput. I have several of these receivers and what I did was get the SRR and the SW-3 confused. I also have a 1-10. T SRR has 3 tubes and one coil. It is a super regen designed for at the time 5 Meters but they also made HF band coils for it so if you pull tte quench oscillator tube and pluug in the correct low band coil you got a simple low band regen.
Any way after figuring out I picked the wrong receiver and pulling the correct one out of the box I hooked up my HB power supply and I have been listening to 4 Meters all afternoon. I'll need to try the SRR someday.
I have coils for the SW-3 which are in original boxes marked SW-5. I think they should be the same since the SW-3 and SW- 5 are the same with exception of the audio stages I think.

Picked up my TCS 12 today. The transmitter looks good. Nothing burnt and no odd stains or smells. It does have a non stock MA meter. It should be a small black round one but it has a square pastic one (300ma) installed. I had hoped I had a replacement but mine are all too big. This one is the small meters with an 1 11/16" face. That is the good news. The bad news is no cabinet. It came mounted in a steel cabinet with a serious hb PSU built underneath. I dont wish to run the tx out of the cabinet and I understand the TCS rx and tx cabinets are interchangable so I will pop the TX into the rx's cabinet and see of my tin banger friend can make me a duplicate for the rx. I haven't tried powering it yet. Tired from the drive and don't feel safe today. Some damage in shipping PSU had a busted 5u4GB. I happen to have a couple in stock so I cleaned up the broken glass and replaced it. One of the modulator tubes was out of its socket so I reinstalled it after making sure it was good. Anyway I now have my Collins station. Just have to get it all working now.

Tim, I assume you mean 40 Meters. Glad you got it sorted out and working. What did you do about the B+ voltage from the power supply? 300V is way too hot; I think the first thing to complain would be the voltage divider resistor, which would fail open. (They often do anyway, but why accelerate it?)

Don, I picked up a TCS-12 from someones junk pile a couple of years ago It had a bunch of those paper caps in mica looking cases. Almost every one of them was shorted or leaking. The band switch contacts were pretty ratty too, but I got it working pretty good.

The TCS was always a favorite with me. It was my first short wave radio. I was 14 when I stole it out of an amphib tank. I built a power supply for it, and even wound a 12V winding onto the power xfmr. Wish I still had it. It was in better shape than the one I have now.

Hello Don,
? ? ? ? ? ? ? ? The very best of luck with your TCS-12 station. I just wanted to let you know that there were two cabinets made for the "TCS" series. One had them stacked horizontally, and the other one had them stacked vertically. I have a TCS-12 rx and tx with the vertical stacking cabinet. I think it may haver been made for submarine use as a backup station. Gett5ing back to the TCS, they are fun to use and will do around 20W+ output on AM phone, and a little bit more on CW. The power supply I use is from an old GE deskmate "Progline". It seems to work very well with it.

The best of luck with your TCS and hope to hear it on the air someday.?

Mod-U-Later,
Joe Cro N3IBX

Yes My Italian (COSREM)friends have warned me about the Caps in the rx especially. I have replaced enough to get it working. The TX looks very good, almost NOS. Nothing bent or mutilated. Lacing all good and unmolested. I know they are not favoured for Cw because of the clicking relay although my Knwood also does that so it may not bother me at all. The PSU is very HD however I havent quite firgured out it yet and dont want to apply any power till I understand its design. Power requirements are identical to my ARC5s (also 1625 tubes) or my No 19 however an extra PSU never is a waste. It is ugly though so may get a new shirt (cabinet)
I have been using the rx a lot the last week. It works quite well and is very quite despite its sensitivity. Still have to get the BFO working. Been listening on 160M a bit as these rigs will do 160 80 and 40. Today would have been Dads 93 birthday so it is a good weekend to get it since I bought it in his memory and with his money. My brother has promised a photo copy of Dads No #1 Wireless School Wireless Mechanics Instructors certificate which I will frame and hang above the station as well as a photo I have of Dad standing under the right hand wing of the Avro Arrow at its rollout which was the purpose for being hired by Collins (he did the radio design)
I got my radio interest from him so I owe him at least that. I am BK ready BTW and can hardly wait.

Don,
? ? ? ? The vertical stack would be FB IMHO. I believe the vertical cabinet was made for the TCS to be used in WWII subs and such. It also saves precious space in the Hamshack. Perhaps you'd want to have a "ART-13" TX next to it - HI! Another FBOM TX from the era.?

I stand corrected on this and perhaps someone on the reflector could clarify it, but I think the "TCS" system was used in some of the "PBY" flying boats. I also think they were used in amphibious landing craft of the type that was used during the invasion of "Normandy" on 6 June 1944.?

My point is they were small and very versatile to get the communications job done. A stock TCS TX with a 4 to 1 balun on it can tune a 15' whip on 160M. They use a variometer on the output of the tank circuit and have plenty of "L" to tune just about anything.?

Another FB thing about them is that the 1625 tubes used are all interchangeable. If your final tube became inoperative, just pop a tube out of the modulator and use CW!

What's not to like about a TCS? I think everybody should have one!

Very best regards,
Joe N3IBX

Well here is the station. Must have been a big temptation just to nix the mod and make a quad four !
Anyway when I first got my ARc5 set I bought a dozen NOS 1625s of ebay in boxes an still have 14 of them so Hopefully I will be ok for now anyway. Same outputs as my Arc5s but I have no modulator for the ARCs5 so built one , a series mod which works well but robs Hi voltage as it is powered by its seriesed connection. It works pretty good and I was using it it a few times on 80 this week with KA2J and the group. Dave KA2J helped me sort through it originally by spending some time in on air testing with me and I have not forgotten his efforts. The TCS has its modulator on board and is as I understand screen and plate modulated simultaneously. So it should pack a bit more punch. I was worried about no 160M antenna but as I understand your post, it should be able to tune my 80m longwire easily. So power out on Am should be similar to what i know get on the No 19 after my modification to the drive control hobble. Perhaps a but more then the 19 but in the ballpark. And I can use it to drive my linear if need be on 80M or 40M. I hope it goes well. Still trying to figure out the wiring from the supplied PSU. I think it wont turn on unless plugged into the TX because of the power switch but want to be dang sure before I try it. Also discovered the Mic/key plug is that odd small one. I have one of them here but will swap it out for a 1/4" because i have about a 1/2 dozen carbon mics here anyway used in .... well some will remember.. another great radio adventure. The ARC5s and the No 19 use crystal mics but with no real speech amp or pre-amp the TCS wont.
Anyway tis fun.

Ready to go for BK...160-40 (attached pics). Solid-state, variable, regulated, HV power supply ala N6GA, eBay filament supply, and twin #27 tubes in a modular fashion for lightning fast band changes :)

HV and filament heat through RG6 and F-connectors, coarse (500pf) and fine (90pf) variables connected with jumpers, plate/link coils from #12 solid Cu also connected with jumpers, and a Bencher BY-1 in SK mode (cathode, 25v across the key, with 200vdc on the plates). Shunt fed and a 10K grid resistor with a parallel 220pf cap.

Thanks for the help with the link. I'm now using 2-4 turns instead of a dozen, into a MFJ tuner. On 80, my QRP wattmeter says 2.6 watts out into 50 ohms with 6.4 watts in (i.e. Ip = 32 ma), but the tone suffers a bit there. The HV supply displays negligible sag, but I can get a big whoop with tight coupling (~3 watts max at 200vdc).

Inverted L on 160, dipole on 80, 2el wire Yagi (west) and dipole on 40.

Thanks to all for the help! I have lots to learn and hope to play around on the air during the week. Forgive me if I maximize output power in the BK and sound "vintage"; it's just a big thirst for high QSO rate!

73, Dean, NW2K

From: James Sweeden
Topic: 14434 Message: 14434

I have my TNT Hartley built to a point where I think I am ready to test it. From the reading I have done on the web I believe it can be tested for oscillation without connecting anything to the antenna coil. Is that correct? I can very my B+ supply from ~ 100VDC to ~250VDC so thought I would start testing with it turned down. If I wanted to connect it to a dummy load should I use a 50 ohm load or would a light bulb be okay? As far as connecting it to an antenna I am at a total loss. I use a 20 meter EDZ fed with window line for the 40 meter band so want to know if the Hartley can be connected to that directly or does it need to be run through a transmatch? At some point I am going to want it to share the antenna with a receiver so will need to figure out how that is going to work also. Some of the options I have are - coax relay(electric), coax switch(manual), knife switch, Johnson Matchbox(I think it has a relay to switch between receive and transmit but haven't checked that out yet). Any help you can give or point me to will be greatly appreciated and if there are other things I should know will be happy to hear about them.

I am looking at all these questions and thinking that building the transmitter was the easy part!

Thank you!

73,

James/KB7LJP

I use a sniffer for a quick check. A Sniffer is a loop of stiff wire soldered to a flashlight bulband fstened to a wooden stick (Paint stirrers are wonderful for this). You hold it near the coil as though it were another loop but an inch or so away and press the key. if there is RF it will light. If not it wont. 100% reliable. I itlights with reasonable brightness you are in business and only need to figure out the freq . I use a knife switch from Lowes (science project drawer in hardware) in my endfed antenna single pole double throw since I am only dealing with a single wire. If double just use a double pole double throw. I can easily reach it from my chair when operating. I find it very convenient. If I know your testing freq I will listen for you. Depending on your antenna coupling you may be able to put a signal out but te antenna matcher will be a good help and cover you butt to some extent for extra emissions. In you case with a too short wire I would use it. Set it up on you normal radio on your choosen freq first then hook your Bk rig up and it should only need a minor tweak if any. I will check back a few times to see if you post Ur freq so I can listen for you.
All the best Don VE3LYX

Howdy again Tim, Another tidbit re: SW-3 coils: They came in 3 basic varieties, as follows:
Type 1 (earliest) - color code is found in 3 grooves on the top rim of the coil form Type 2 - Numbers are on the bottom of the coil form denote the frequency range Type 3 (Latest) - I have never seen one of these but I think they have numbers on the bottom
I also have coils in the boxes marked "SW-5" and they seem to work just fine in the SW-3. Allcoils are basically the same but the number of tickler turns vary somewhat. The newest type having theleast number of turns.
Anything I can hear on my ICOM-7700, I can hear on my SW-3. Good luck with your restoration.Take care and stay well.

Any way after figuring out I picked the wrong receiver and pulling the correct one out of the box I hooked up my HB power supply and I have been listening to 4 Meters all afternoon.

Tim, I assume you mean 40 Meters. Glad you got it sorted out and working. What did you do about the B+ voltage from the power supply? 300V is way too hot; I think the first thing to complain would be the voltage divider resistor, which would fail open. (They often do anyway, but why accelerate it?)

It works on CW (tuned up on 3580) output isnt huge but enough.havent figued out yet how the mike is wired. I was keying through the PSU connection that came with the set. One jack which says key or mic on the set proper. I assume one tip contact goes to the mic wiring and one goes to the keying relay. Which one though? Even after I sort it out I may install a separate mic jack. Don't like potential trouble spots.

Hello,

As some of you may know*, over the past 3 weeks or so I've been building a mid-1930s superhet communications receiver. It's been on "the list" for a few years now, but for whatever reason it suddenly became the most appealing project on the list, so I decided to "strike while the iron was hot" and get busy.

Topology is as follows - Jones "Super-Gainer" front-end with a type 57 regenerative mixer and 56 oscillator, two IF stages with AVC at 455 KHz using 58s, a 2B7 diode detector and 1st audio, 56 split-load phase inverter, PP 59s in the audio output, 5Z3 rectifier, and 24A BFO using the Dynatron circuit. 10 tubes in all. I am building it on the carcass of a "Columbia SG-8," which was a TRF AM broadcast set from 1929. It was my grandfather's, he had picked up the chassis and matching electrodynamic speaker on Radio Row in NYC in the 1930s. He had torn it apart and it was the foundation for many projects by him, and then me, as far back as I can remember but has been neglected as an almost bare chassis for the past 40 years or so. The only parts I am using that are original to that set are the chassis, power transformer, filter choke, and the speaker which still works and sounds great.

About two weeks ago I had completed and was testing the front end only, using an external power supply and feeding the mixer output into a BC-453 tuned to 455 KHz. Last Tuesday and Wednesday I finished it up to the ("2nd") detector and was feeding its output into an external audio amp. It worked extremely well (about as well as any communications receiver of that era that I own, and I own a few), and I used it in a QSO with W2PFY on 40M AM. So far I have only wound coils for 40M. Actually they go from 40M to almost 20M; with a little tweaking of the coils I think I'll be able to get them to cover both bands. Eventually I'll wind sets to cover at least 160M and 80M as well.

As of this morning the power supply and audio sections are just about done, and the BFO will be the last section to complete - not counting a front panel. A Pilot drum dial will replace the large pointer knob on the bandspread tuning condenser. I am waiting to install it last to reduce the possibility of damage to it. The 2 under-chassis photos show the progress that has been made in the past week - actually a little less than that.

*it's about all I've been talking about on the air recently

Well that would be due to my lack of knowledge I am afraid, somehow I was thinking the TNT was a variation of the Hartley design. I do have lots to learn so am very glad to have such a great support group for help! What I have built is a TNT so maybe what I was reading about testing with no load doesn't apply?

Don, thank you for the recording. Eric, thanks for the Q. Andy, thank you for the report. I made a 1/2 dozen Q's and am there again.

Is that what these rigs are supposed to sound like? When I couple loosely, I can get a great note, but very little output. When I couple more tightly, I get the "whoop" like in the recording. That was 6 watts in, ~2.5 w out.

Is 250vdc x 0.050ma too much the pair of #27?

Thanks! 73, Dean, NW2K

de James/KB7LJP ... What I have built is a TNT so maybe what I was reading about testing with no load doesn't apply? Would still apply.

I do have lots to learn so am very glad to have such a great support group for help! See below AWAGroup.

I have my TNT Hartley built to a point where I think I am ready to test it.

From the reading I have done on the web I believe it can be tested for oscillation without connecting anything to the antenna coil. Is that correct?

I can very my B+ supply from ~ 100VDC to ~250VDC so thought I would start testing with it turned down.

If I wanted to connect it to a dummy load should I use a 50 ohm load or would a light bulb be okay?

As far as connecting it to an antenna I am at a total loss. I use a 20 meter EDZ fed with window line for the 40 meter band so want to know if the Hartley can be connected to that directly or does
it need to be run through a transmatch? See second sentence of #3 below.

At some point I am going to want it to share the antenna with a receiver so will need to figure out how that is going to work also. Johnson Matchbox (I think it has a relay to switch between receive and transmit but haven't checked that out yet).

I am looking at all these questions and thinking that building the transmitter was the easy part!

Hello, My name is Jim. I recently joined the group. This is a picture of my 40/80 meter Hartley. So far I have had 8 qso's with it. One was Hartley to Hartley with Bill K4JYS. The greatest thrill for me was a regen contact with a xtal control transmitter. This has that beat! Maybe, at some time, I can make a Hartley, regen contact. Almost forgot, it's a type 27 tube and about 4 watts out. 73 Jim

Dean,
You may find that a less coupling (about 50%-70% max power out) will be easier to copy. I found that moving the ground tap back toward the grid end of the tank reduced power a bit but cleaned up the note, and moving it toward to plate increased power but often at the expense of the note. Moving the location of the tap also seems to affect the drifting a bit. Also try reducing the plate voltage. You might find that at 200V it regulates better and the chirp goes away.
Lots of variables to play with, but you have good antennas and even whole watt out should be fine.
FWIW, Dean was my first QSO with an all-1920's RX and TX. I'm trying out '99s for detector and one stage AF so that I can use dry cells in an attempt to cut down on the hum...how do you guys with SW-3's do it?
I'll be around later tonight (say 10pm EST) if anyone wants to tune up some radios.

I've attached a picture from the ipad. I'll take some better ones as things get cleaned up and we get near the weekend. Right now things are little crowded.
On the left is the 1924-style 80M transmitter (with slightly more modern tubes at the moment). You can see the green light of the recapped Heathkit PS3 is underneath the bench providing the B+. Behind the TX is a variac from the AWA flea market attached to a 7.5V filament transformer (thanks Lou!) which is dialed down to 5V for the parallel 71A's that are in there right now.
On the right is the movable-tickler "low loss tuner" with detector and one stage AF with CX-299's. The design generally follows 1924 practice (the GR transformer I'm using actually came out in March of 1925), most specifically a tuner in the December 1924 QST using parts I had available. It's built into the carcass of an old NBD clone, which is why you see all those holes in the panel and why the tickler is mounted the way it is. I'm going to make it a little nicer, but it's probably good enough to try to use. You can see the knife switch in the upper right which will allow me to switch to the K3 receiver if I need that modern single signal passband.
I'm using Cannonball Master headphones that were manufactured in the metropolis of Springwater, NY sometime in the late 20's. (You can ask NW2K about Springwater--he lives there.)
I'll try to be around 3560 and up a little after 10pm, avoiding any nets that might be in the area.

Don, Thanks!

I was fortunate to make some QSOs on 160, best was Maine and there were several RBN spots. Now I just need to work a bit more on 40.

As I was telling Andy K0SM, there are too many darn "knobs" on these transmitters. Most of which I have no clue about. Learning a little makes you want to learn more.

Larry,
I had a power supply for another receiver project so I modified it with a 2.5V transformer and it all seems to work just find. The B+ is running about 160V DC and the SW-3 seems to like it. The SW-3 does have some nasty microphonics though. Several years ago I built a 40 meter tube regen from a QST article. Used a couple of maybe they were 12AX7 or was it 12AU7s. It has great sensitivity and great stability. Built it just for 40 Meters so the bandspread covers just 40 Mc. on the whole dial. Much much better then the SW-3.
I need to look into modifying the SW-3 coil to cover the 40 band the same way. The coil set I have in it now is the 4 to 8 Mc set are thereabouts. and it is too broad to do any real CW work. I had intended to use the SW-3 (and when I get it working my SW-5) as active used receivers on 40 CW.

I picked up a Homebrew PS at an estate sale. It's a standard full-wave rectifier arrangement with a 5U4 with an 800V CT secondary. It has a power switch and fuse in the primary *and* a separate switch on the secondary center tap. What would be the purpose of a C.T. switch? Maybe let the rectifier warm up first before drawing current?
The thing has several safety issues, so I'm gutting it down to the chokes and transformer and working from there, but I'm just curious why someone might do this.

Yep. What Jim said.

Only issue with that approach is it's important that the xfmr construction is such that the CT tap is adequately insulated from the xfmr frame, because when disconnected the CT floats at a high potential relative to ground.

GA Andy, You put your finger on a reason to use a CT switch. With the exception of bridge rectifiers and low-voltage supplies,I always include a CT switch in my homebrew supplies. Be forewarned that the windings are hot and should not berelied upon to make the supply "safe" while servicing or trouble-shooting. It is only safe when the AC Mains switch isoff and the line cord disconnected.
  I do not use tube rectifiers of any kind. The warm-up is intended for the unit it supplies. Having said this, if the unitbeing supplied is all solid-state then the CT switch becomes superfluous.

Jim,
I think that was the purpose.
That was one of my safety concerns....it looks like the B- is tied to the chassis on the other side of the switch as it was wired.
The plan is to put two pairs of 1N4007s in a socket so that I can use a variac for a variable B+ supply but still retain the ability put in a 5U4. As you surmised, Larry, the filament supply is on the same transformer, so a variac isn't too useful if I want a wide range of voltage. It's going to be choke input for better regulation, since this is going to be an extra supply for BK, hopefully.
The guy who had this built everything and labelled everything. This includes when the filter caps were tested: January '68 and March '88. (They'll be replaced!)

  Yep. What Jim said.

Only issue with that approach is it's important that the xfmr construction is such that the CT tap is adequately insulated from the xfmr frame, because when disconnected the CT floats at a high potential relative to ground.

The station looks FB, Andy.

Perhaps the larger hole in the RCVR panel can be filled with a meter to show filament voltage, as was done back in the day? and the smaller hole filled with a switch in series with the filament(s)?

Nature abhors a vacuum (except when confined within the envelope of a tube, of course)!

Larry,
I actually have new panel cut the size I want for the finished product--I just haven't gotten to it yet as I'm still trying to figure out some better. I'm going to keep this panel around since it already has holes conveniently drilled for National DX capacitors. The big hole was for a meter, and I still have it. It's just on the wrong side of the circuit since there is no RF amp tube to measure!
I'm probably not going to do more construction on it before the BK, but I'll do my best to try to use it as is. I don't think I'll be able to search and pounce with it. In fact, I don't think the idea of a separate bandspread knob was around in 1924, but they did do things like cut or remove plates from condensers. I haven't done that yet, but I probably will pull a few plates from mine to see how much it improves. As it is now, 3.5-4.0MHz fits in about one whole rotation of the vernier, or about 1/5 turn of the condenser. With a passband several KHz wide you don't need real fine tuning--just good enough that when you tune to a station and let go of the knob he's still there, somewhere. When Lou and I were tinkering with it a couple months ago we joked that it was fabulous for early 1925 when there were only five or six signals spread across the band! I listened to the MSN on it a few weeks ago, and it was stable enough for SSB reception if one took care to get it tuned in just right.

From: James Sweeden
Topic: 14434 Message: 14479

Built the sniffer and powered up the transmitter. Holding the sniffer near the plate coil while keying lights the bulb more than a dull red so that seemed good. Found the signal on my receiver (lower end of 40 meters) but the tone is not good, very buzzy. The receiver is about 8 ft. away with nothing connected to the antenna input. Connecting a power meter and 50 ohm load to the transmitter doesn't change the tone. My plate voltage is 100VDC and the plate current when keyed is ~15ma. The needle on the power meter just barely moves. Checked my wiring again and don't see any errors. I did use .0047mfd ceramic disk caps across the filament as didn't have anything else that value so not sure if that might be a problem. In the grid circuit I used a dipped silver mica cap labeled 250pf across the resistor but I didn't check it before soldering it in so wonder if maybe what I installed was 25pf. It's not real easy to remove so thought I would ask if a 25pf cap might cause the problem I am having before doing that.

Thanks for any help you can give.

James....both the grid resistor and the cap can be quite critical in influencing efficiency as well as keying. It's well worth experimenting with these values if everything else seems in order.

first before doing anything else using the sniffer find the spot where your bulb glows the brightest. Then check it on that freq on ur rx. check your grdlk resistor for value. Make sure your heater voltage is in the ballpark.
100v isnt much but since you are making rf ? Try less coupling on the antenna coil . If all else fails hook it to Ur antenna and give us the freq!

You can connect the cathode lead directly to one of the filaments leads and it will all work . The best way to do the cathode is a splitter. A low value resistor(20 to 50 ohms) from each side (each filament) joined at the centre with a .01 across or parallel with each resistor and the cathode lead coming of where they join. Some of my old books (1927 etc) suggest using Christmas light bulbs for the resistors. (I use 6 volt pilot lamp bulbs) Any value of cap from .001 to .01 will work for resistor bypass HOWEVER it is not necessary to do it that way. Just connecting it direct will work especially for your first go round. Refinements can come later. 250pf may be a bit gentle for a TX although for a regen (same circuit lower voltage) it would be good. however it should not cause a problem where as too much could potentially be difficult to tame. As mentioned before and by others gridleak resistor can be an issue. Also BTW a accidentally resonant RFC can give a lot of grief. Just some stuff I remembered while I was pretending to sleep.
Tested my new one last night. Worked N8CT so it is good to go.

James,

With my TNT I get a bunch of weak responses in my receiver on frequencies other than the "real" one, which is much, much stronger than the others. The notes of the weaker spurious responses are typically rougher than the one that's "real." Make sure your receiver is tuned to the frequency that gives the strongest signal on the S-meter. If you have a frequency counter put a short (6-8") insulated wire on the input and sniff around the tank coil with it; it will indicate the actual output frequency. (I use a 2M "rubber ducky" antenna on the freq. counter input.)

I agree that 25 pF would be way too small for the grid DC blocking cap, even 250 pF seems too small, as Don indicated. I'd think something between 2000 - 5000 pF would be more appropriate.

Unfortunately I will not be on for this year's BK event...the first one I have missed in several years since first building my TNT.

My xyl, who has been in Florida for the past 2 weeks will be returning home on Saturday night and it's probably not the best idea to quickly disappear into the shack for the evening :-)

Unfortunately, the second weekend is the 160m Stew Perry event, one which I have always been able to operate in but this year, both BK's were moved back one week. This allowed participation in the ARRL 160 CW which had always been a conflict but unfortunately has now created a new conflict with the very popular 160 SP event.

Hopefully this notification will prevent several of you for searching for me during this year's BK!

You will be missed but we understand!

This brings up an important point. All 160m BK activity this year
needs to be on the FIRST weekend, NOT the second as has been the
case in past years.

I plan to participate but it is going to be difficult pulling myself
away from projects. I am in a particularly productive building
spree, though it is not OT stuff.

From: JAMES HANLON
Topic: 14490 Message: 14490

I run a 10 Hartley myself, both "barefoot" and as the oscillator in my MOPA. I do not have any particular trouble with a hummy signal even though I do run 7.5 vac on the filaments. However, in the BK I have noticed that many TNT rigs sound very hummy. Is it perhaps related to that particular oscillator circuit?

On the SW-3, mine has never been microphonic. Perhaps tapping the tubes or other potentially offending parts would turn up the problem. I run a home-brew, VR tube regulated power supply for my B+. It probably helps the receiver stability when I key a big rig like my Globe King 275 plugged into the same power outlet.

I am using a 71A. The plate the tuning cap is mounted on is really two plates spaced apart from each other to form a cap to get me in the 40 meter band (if that is really where I am).

Thanks for your help.

James/KB7LJP

P.S. Tried sending this direct several times using 2 different addresses and 2 different e-mail programs but received delivery failure notice each time, not sure what the problem is so am sending to the group. I have checked my freq with a counter and it, like me, thinks I am in the 40 meter band.

Tks James,
First reaction to opening the photo was, "Nnnice!". You seem to be an old hand at tank coil winding.

I am using a 71A. I've a rig using a 71A. Found that the best grid leak value to be in the 38K range. (The best resistance value was rather broad.) I determined that value by using a 50K rheostat in place of the fixed leak. Key down, I tuned the rheo looking for the lowest Ip, best signal tone, least chirp and drift.

As well, I found that 225V B+ was not a problem, but used 200V when operating the rig. At 200V the output was, as I recall, 3Ws under proper loading.

I am wondering if you will achieve the Kelley legal input of 10Ws with that tank and antenna coil mount spacing. After you've gotten the rig operating OK and your satisfied with the output, fine, but if to low, suggest that you temporarily mount the antenna coil outboard closer to the tank for a comparison. As has been mentioned here already, the greater the load, the less Collins like the signal quality. So what. Load 'er up for that 10Ws because the Kelley Gang here is expecting big things from Port Angeles, Washington.

The plate the tuning cap is mounted on is really two plates spaced apart from each other.... What is the maximum capacity of this plate condenser?

P.S. Tried sending this direct several times using 2 different addresses and 2 different e-mail programs but received delivery failure notice each time, not sure what the problem is ... Nor do I.

I have checked my freq with a counter and it, like me, thinks I am in the 40 meter band. You're almost home, James!

Surely there is a good way to do this, but web searching is getting me nothing but noise of how to repair or replace a socket that I already loose; I want to separate the base from a well glued tube. I'm making a 5U4 replacement and I have a few junky, dirty tubes with octal bases that I can sacrifice, but they have tight bases!
What's the best way to get off a socket without blood? Any (relatively safe) household solvents do the trick?
Thanks,Andy K0SM/2

Andy,

Part of the base adhesive chemistry is shellac. Soak the base in a small cup of De-natured alcohol overnight. In the morning, shake out the alcohol from the base and begin wiggling it. As it loosens dunk in alcohol and continue. when it is real loose, shake out remaining alcohol and start to de-solder the pins while twisting the base. Move from pin to pin with the soldering iron, with a little luck, all the pins will de-solder and the envelope will pull free leaving the pins almost clean. The remaining base adhesive should be crumbly and can be removed with a a soft scraper or screwdriver. A final cleaning of the pins and it should be fine...

I have waned to replace bases on a few 250's and a couple of 245's and use porcelain bases. However, I need a cement that won't break the glass and can take the heat as well as be RF transparent. I am aware of Sauereisen Cement but was hoping for a hardware store alternative like furnace cement. Anyone have something that works?

GL with diode replacement.

Thanks for the kind words.

I will change the grid leak resistor to something close to 38K. Can that be wire wound? I pulled the cap across the grid leak resistor to see if it was 250pf or 25pf and it measured 250pf which was what I thought I was installing. What value does your 71A rig use?

I should have left myself a little more room on the left hand side of the board but when I get it working will devise a way to move the antenna coil for tighter coupling.

I think the tuning cap is about 120pf and the whole assy. about 470pf. I placed a 470pf silver mica cap across the tank coil after winding it and tested that with my grid dip meter and found I could tune from just under the 40 meter band on up. The setup installed does the same starting at about 6.7Mc.

Thank you for your help!

73,

James/KB7LJP

This is the radio Dad was most known for. The ARC552. It is in there somewhere, trust me. I think it was also know as "the gas can radio"as it was a plug in deal I believe.I was 9 or 10 years old then but already had my rocket radio and a couple of other Remco plastic specials. This is where my radio interest began. I have been in this plant many times , usually Saturday mornings.
The company also built 75A receivers at the Bermondsey Road plant.
So the Collins station for me is in Dad's memory. My brother Dave who was executor said Dad had an ARC552 set but somehow in the frey of his passing it has vanished.
I well remember the days when they were designing this radio which included a free trip for the family to California while Dad had to spend days at Lockheed making sure the radio design would fit the Fighter jet cockpit design.
Never heard Dad ever say a bad word about Collins. I always wanted a Collins something ever since. Now I have it. Dad would be pleased I think.

Hi James,
I will change the grid leak resistor to something close to 38K. Something close, yes. 10K (for a 210) and 50K (245) were not OK.

Can that be wire wound? Yes.

I pulled the cap across the grid leak resistor to see if it was 250pf or 25pf and it measured 250pf which was what I thought I was installing. 250pfd. / .00025 is the norm.

What value does your 71A rig use? .00025 Sangamo.

I think the tuning cap is about 120pf and the whole assy. about 470pf. I have never seen or heard of this approach. Clever.

Thank you for your help! Glad to help.

14507. G3ZDQ Hull Hartley Transmitter for the Bruce Kelly QSP Party

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-08 19:20:33 UTC
From: g3zdq@...
Topic: 14507 Message: 14507
Attachments: 5 described; binary payloads are missing from this source WARC

Hi my name is Ian G3ZDQ, licenced since 1968, I've been building and collecting UK radios and transmitters for quite a while and Eddystone radios for the last 15 years. Checking the Eddystone web site, I saw a request had been posted for Ceramic Beehive Insulators. Over several months the posting remained, seemingly unanswered. Now in addition to collecting and renovating Eddystones, British RAF receivers, KW and various others, I also have an interest in radio components and have collected quite a few early components, some unused and boxed, including two unused Eddystone beehive insulators. Many have been given by radio enthusiasts who have reached that point in their lives where they suddenly realise they either need to pass the bits on or heaven forbid dump them in the trash before an unthinking relative does! So that's how I first came to know Lou VE3AWA, I replied to his posting and a whole new chapter unfolded on my radio hobby. The wonderful world of home built vintage transmitters. Thanks Lou!

About 2 weeks after the beehive insulators arrived in Canada a parcel arrived in my back porch. You can imagine my surprise. Inside was a beautiful UX-171A triode valve, circa 1927, valve holder, a data sheet and a note from Lou, with a few words " a little nudge". Well, that valve had to be used and four months later you can see the result. My interpretation of a Hull Hartley transmitter, which I am hoping to use in the forthcoming Bruce Kelly QSO Party this coming weekend in December 2016.

When Lou sent the UX-171A valve, there was no suggestion as to what form of transmitter to build, so I did quite a lot of searching about the BK QSO Party and what types of transmitters were being used. There is an amazing amount of information out there and some superb photos of the transmitters that have been built and used. Lou sent me some photos of the many types of transmitter that he has created, which gave me a clue as to how to start. One particular photo from Wireless World Review August 1924 shows a low power rig, which uses similar components and construction to mine, although I only saw this article after I had finished my rig.

I eventually decided on the Hull Hartley design. Not quite sure why. It just looked right and gave the prospect of a stable signal for my first attempt. I used the circuit and papers from “Building a Classic – The Hull Hartley Transmitter” (VE7SL) as a guide. Once I had the circuit my first challenge was collecting the necessary components and not just any components. It had to look right as well as function! I searched my collection and my junk box and amazingly came up with everything I needed apart from the main coils. In the garage I had an early circa 1930 half completed home made receiver built on wooden base, which I decided would make an excellent base for my transmitter. The wood was a little distorted and as stability was is fundamental to achieving my goal, I decided to strengthen the base with 3/4 inch ply. After sanding and applying several coats of Danish oil the finished

base looked the part, a rich golden colour, showing the grain and the old screw holes from its use in the receiver.

Prototyping the layout was great fun and took many days … many days! The Hull Hartley design positions the valve on top of the main tuning capacitor and also many of the other resistors and capacitors to reduce lead lengths and improve mechanical stability. I did not have any National DX variable capacitors but what I did have were several precision capacitors mounted in wooden cases. One of these had a tuning dial which offered a Vernier scale. The wooden case allows the valve base and the grid and filament components to be mounted in a similar way to the original Hull Hartley design. The grid capacitor uses an early Lissen component which has had the pitch removed by carefully heating with a paint stripper gun. A 250 pF silver mica capacitor 500 V dc working has then been carefully fitted within the old case. The grid resistor was initially 10K ohm and gave a roughish note. After testing and a suggestion by Lou this has been changed to 33K. The note is okay now but does change a bit every time I power up!

The transmitter is putting out just over 1 watt into 50 ohms. I tested it with Lou VE3AWA on Friday 2nd December 2016 using a 40 meter Inverted V. So far we have not made contact, but I will be monitoring the 40 band between 22:00 and 03:00 GMT during the next two BK weekends. So Please keep an ear out for an interesting CW tone from the UK! Apart from monitoring the usual 40 meter BK frequencies, I will also be operating between 7.050 and 7.060 MHz. Unfortunately the 7.040 QRP frequency is likely to suffer from digital interference.

Apologies for the long introduction but I hope you find the photos interesting.

I've successfully used the high-temperature black RTV silicone that the
auto parts stores sell for gasket sealing. It remains pliable so there
is no risk of glass cracking from thermal expansion coefficient
mismatch. I've also used it to re-glue plate caps on transmitting tubes
such as 812As, and it seems to hold up OK.

73,
-Larry/NE1S

?Hello All,
? ? ? ? ? ? ? ?There will be an AM Operating event this Sunday December 11, between 7AM and 5PM on the usual AM Operating frequencies on 40M and 75M. This is being done in celebration and recognition of the first American signals being heard across the Atlantic Ocean in Ardrossan Scotland ninety-five years ago on December 11, 1921 with 1BCG in Greenwich, Ct. being heard the first, loudest and most often. There were a total of 26 US stations beng heard in Scotland during that momentous event.?

The commemorative?AM station will be "N1BCG". It will consist of a E.F. Johnson "Valiant" transmitter and a National "NC-303" receiver with a little over 100W output into a conventional type dipole antenna.?

If you hear N1BCG calling on one of the popular AM haunts on 40M and 75M; get back to them and exchange signal reports, audio quality, and how much you enjoy AM. ?It won't matter whether you're running vintage gear, a "ricebox", a Flex radio or even Class E. equipment. Let them know of your support for the mode.?

I was told of the above operating event by Norm Fusaro, W3IZ of the ARRL. Many thanks to Norm for passing this information along. I hope to hear you on the bands!

Mod-U-Later,
? ? ? ? ? ? ? ? ? ? ?Joe Cro N3IBX

Hey Dean,
Hope to wrk you on TB as well as other BK bands.
I will be QRV on 160 around the following times
(+/- depending on how business is on other bands):
8PM, 10PM and 12Midnite. These times are not
nailed down and can go to 160 most any time. Will
be using separate station on 160.

If the SP is the following w/e, guess this w/e will be our
only workable time.

Date: 2016-12-10 11:26:54 UTC
From: Thomas Höppe
Topic: 14525 Message: 14527

Hello Brian!

I had nearly the same plans. I wanted to take my most powerful WW2 spy-set replica and try to make QSOs during the BC party. I have beverage RX antennas for RX, but I think I need to good signal to get heard. Then I checked the rules on the homepage. QSOs with XTAL controlled stations don□t count. The stations getting called by non rule conform stations are advised to □point them to the webpage□. Calling in with XTAL controlled 6L6 will only waste valuable time for the rule conform station that could be used to make valid QSOs inside NA. With 10W input limit it will be hard to make valid QSOs from EU to NA. But this are the rules we have to accept.

My Hartley only makes 2W out. So I decided NOT to try.

My plans are to make a callup for tests to cross the lake around Christmas.
What do you think about that?

My 2 cents ..Tom, DJ5RE

WAS???????
You could work Ian in UK. He is ready to roll. Who knows we might hear U .
I will be late starting as I have to attend a Christmas party late afternoon. I am going to start out on 80M with the Dreipunkt (Hartley) till the D cells get tired then I think the Rattrap also on 80M. At midnight, the monster hartley and it has been copied in Europe before BTW. It runs on 40m And usually around 7035 to 7050 if possible.(no traffic)

14529. Re: UK active BK event today

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-10 12:24:14 UTC
From: Thomas Höppe
Topic: 14525 Message: 14529

Yes Don, you red right.

I don☐t have the suitable setup. My Type 27 Hartley is not powerful enough.
I always had in mind to use one of the spy radios.

After checking the rules exactly I found out it makes no sense. Possible QSOs with the spy sets will not count. Imagine, you are not the winner as you wasted your time working me, and the QSO does not count? I could not sleep anymore!

Most of my replicas are late 30☐ies/early 40☐ies.

We☐ll have fun around the Christmas days! I checked 160m at DL0AO yesterday,
the winter RX antennas work great! I worked 28 US-Stations in one hour,
including 3x W7 callsign area. One East-Coast station was ☐QRP☐ .5W!

If you want to try although it will not count, I could offer a sked around 05.00 UTC on Sunday for those who want to try although it will not count.

Big Brother will watch you in any case ;-)

Hi again!

Brian is right! There might be stations interested to try DX, even when it does not count.

I want to offer skeds. I would call CQ tomorrow, 11.12.2016

It could look like this:

05.00- 05.30 UTC I call CQ AWA at 7035 +/- QRM, using a modern rig and 2 El. Beam.

05.30- 06.00 UTC I call CQ AWA at 3565 +/- QRM, using modern rig and beverage system for RX

06.15 until 07.00 UTC (sunrise) I call CQ AWA at 7028-7033 using a 2x Type 27 Hartley with 2W out, RX modern. This QSOs would count! You need a good RX!

So HW?

Please your short answer to know if anyone is interested in that test. We can also repeat that outside the BC party with RX and TX vintage.

Hey Paul,
Sorry you won't be in the BK this year. I am in a bit of a quandary here. It's down to the wire and have never heard anything re. my use of W2ICE/4 in this years BK. Just wondering, when you used 'ICE' in the BK if you received FCC/AWA paperwork regarding it's use. Or, did you just go ahead and use the call. I don't wanna get into any trouble from either so I am sorta hesitant to use it unless I have some 'official' authorization. I've just sent Tim, W1GIG and Scott, WA9WFA emails, but thought you might have some quick advice. Thanks...73 de Bill K4JYS

Guys, No there isn’t any paperwork required. You simply operate at W2ICE/4, just like they pass W1HRX around the country for the AWA AM QSO Party.

So no trouble.

Well I am ready, The Drei-punkt (far right (aka hartley) is tuned up on 3607 and I gave it a quick test. It has a very distinct voice. I can't run it long because the tube is on D cells. Hopefully I can log a couple at least. The Rat trap is at the ready next to it and the J38 key is plugged into the PSU for the Monster Hartley for after midnite adventures on 40M. GL to all. I will be late starting.Hopefully around 8pm my time since I have to attend a Christmas Party first. I made sure everything is ready to go so I can throw my coat off run down stairs and fire up. I am just a wee bit cranked I think.

From: Whitebear1122
Topic: 14545 Message: 14548

Oops I accidentally deleted some of this reply and didn't notice it. I emailed Bill separately with the go-ahead.

The registered FCC holder of this callsign is the AWA club and they have authorized it to be used as a special event by one of the members. So there is no paperwork required nor FCC notification. Once they gave us the approval to have Bill run the callsign, that is all that was needed. They do the same thing with W1HRX, James Millen's callsign, for their AWA AM QSO Party. Often W2AN, AWA flagship station, is heard in the 1929 QSO Party. I haven't heard anything about W2AN this year so I hope to run into them as well.

I will be on late tonight after getting home. I hope some of the guys will still be around since it will be 10:30 or later.. I'll be on 40 meters tomorrow though.

Best of luck to all and I hope to hear and work each and every one of you :)

73, Scott WA9WFA

I just got the push pull Colpitts hooked up and running on 80m with a nice signal. For some reason it sounds pretty rough on 40m so don’t be expecting me to show up with a sweet signal on 40m :)

Bill K4JYS will be operating the Bruce Kelley Special Event Station as W2ICE/4. Bill was top dog last year and agreed to operate as W2ICE/4 this year and put this special call sign in as many logs as possible! This is the 3rd year with Bruce Kelley’s callsign being heard on the air in this 1929 event since his passing. I first operated as W2ICE/0 in 2014, N1BUG Paul operated as W2ICE/1 in 2015, and now Bill K4JYS will have the honors in 2016.

Good luck to all.

73, Scott WA9WFA

Whew...that was close. I was about to pass up this opportunity 'cuz
I just wasn't aware of how it was done....didn't want to do anything
illegal. Thanks to Scott, Paul and a bit of prodding from Lou, I
have the proper guidance and W2ICE/4 will be on the air from
North Carolina.

Here in the last few hours, before starting, does anyone have any
operating time suggestions? For 160m, I plan to be around 1810kc
at 8PM, 10PM and 12Midnight...any need to go past midnight?
I will be running a separate xmtr on 160m, so I will actually be
checking the band at other times as well. On other bands, its hard
to nail down certain operating times. I will probably start out on
40m. May hang out on 40m 'till 9PM or so (there are so many nets
on 80 it's just real hard to find a clear freq...they seem to thin out
around 9PM). Any folks from out west have any operating time
suggestions?

I appreciate the privilege of being allowed to operate as W2ICE/4.
I look forward to working as many stations as possible.

GL...73 de Bill W2ICE/4 - - K4JYS

I expect to be on around 9 tonight on 40, and then tomorrow on 40. Was setting up the station today and the rcvr was as dead as could be. Finally traced it to the shielded lead that goes from the Ant terminal to the W.L. coil. It had shorted out. Interesting thing is even with that I could hear stations

Hello,

First of all, Ian, I am tuned up on 7050 and will start the Party listening for you on that frequency. Will slide up to 7100 up as well of course.

Below is my station for this year. TPTG / 80 and TNT / 40. Will not be on 160 this weekend due to TNT problems on that band.

Carl. I agree with Bill, great station. Hope to CUL.

GL All

Lou VE3AWA

I've added vernier driven Cardwells to the TPTG rig on shelf. Much QSY better.

Subject: Re: [AWA Group] 4 Min.s to go.

Okay Lou,
Listening at the moment on 7.050. Just heard a few very weak tones. Unfortunately some digital again. Will try to find a clear freq nearby. GL.
Nice photo of your station.

Hello,

First of all, Ian, I am tuned up on 7050 and will start the Party listening for you on that frequency. Will slide up to 7100 up as well of course.

Below is my station for this year. TPTG / 80 and TNT / 40. Will not be on 160 this weekend due to TNT problems on that band.

Carl. I agree with Bill, great station. Hope to CUL.

GL All

Lou VE3AWA

I've added vernier driven Cardwells to the TPTG rig on shelf. Much QSY better.

Surprised not more activity on 160M. Band is reasonably quiet. QSOs w/
NY, NC, and MN so far... lots of CQing!

Will resume on 160 at midnight EST, ramp up the power to 20W input!

0710z...

I just spent more than one hour trying to hear DJ5RE. Nothing.

BUT... I can not hear ANY signal from Europe on the whole band. Not one signal. Dead!

I can hear some W stations and some South America...

Earlier I listened for G3ZDQ 2300z - 0200z. Nothing.

Got called by UY5AA on 160M after midnight and power increase to 20W
input (he was out of band down at 1807). Later ragchewed with DF2PY
same rig and power on 160. Shame not more guys have rigs for down
there, seemed like a decent night and QRN was very low. Just 4 BK stns
in the log on 160.

Don't know if I'll mess around much tomorrow. GL to everyone and have fun.

Nice going Eric!

I think the problem may be MUF below 7 MHz. I tend to hear Europe
best on 40 around my sunset. In the mornings the band doesn't open
to the Pacific or Asia until well after my sunrise.

14575. 1929 Party report from Bavaria

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-11 08:37:15 UTC
From: thomas.hoeppe@...
Topic: 14575 Message: 14575

Hello AWA'ers!

As planned, I was QRV this morning. I fell out of the bed a bit earlier as expected (may be my XYL kicked me out...), I decided to drive out to the DL0AO clubhouse a bit earlier. When I arrived there, 40m was totally clean.....I even checked if the antenna is working. Nearly no sigs, just a few very weak stations from South America. Strange! I tried 80m, where the band was alive. Around the QRP frequency I found W8CDX and W2ICE/4. I called them (with modern rig). QSOs were easy....sigs up to S7 using a 170m long beverage to NA for RX. I was running QRO (2x GS35b amp) and a 35m high groundplane (parallel fed), so I was heard on the other side. Reports I got were not as good as expected, so I think it would not have worked using a 1929 TX with max. 10W input. I went on 40m as promised, from 05.00-05.30 with QRO. I called "CQ AWA"....no results. The band was dead. Then, from 05.30-06.00 CQ AWA on 3565. K4JYS came in with his personel call, again easy to copy. This was the only station answering my CQ! I am afraid conditions were good, but there were not more stations awake in the AWA. Bill was using a Hartley, 10W input into a windom. So not an outstanding DX setup. The next timeslot was 40m with the Hartley/3W out. You guess it....again no QSO. Band still dead.
Later I said hello in the low band chat on ON4KST where I learned that W8CDX was Eric, NO3M.
So I ended with 3 (unvalid) QSO's using modern rig on my side, with 2 individual stations. Congrats to Eric and Bill who made it over the pond.
Thanks for those who listened on 40m. We had no chance during that conditions. But it was a surprise to see 80m good for DX with 10W input.

Been calling on 7.050 since 12:00Z. But not heard any AWA yet. There is a Dutch naval contest today until 15:59. So the band is fairly active with strong CW stations on 7.035. Strong SSB on 7.100.

Last night I called/ listened on 7.050. - 7.055 until about 02:30Z. After 01:00 most signals started to fall off and by 02:00 the band was almost dead apart from one Spanish station on SSB. Local noise levels were about S3 at 23:00Z rising to S7 by 02:00. I think the muf was too low for 40 by then.

Am taking another break and will call again at 20:30Z nearest 7.050. Will also listen to see if I can hear and work anyone on 7.035 & 7.100 from time to time.

From: Jim Hill
Topic: 14268 Message: 14581

Andy:
I would be interested in seeing how the Stancor works with your idea. I doubt if the plate current is enough to overheat the secondary winding, and the core won't be going into saturation. Why don't you temporarily connect it in a working receiver and check the difference?

Here's another tip I used years ago; the zap method. Take a receiver power transformer you have in your junk box, connect one end of the secondary to one side of the open winding, and just very briefly touch the other two leads together. There will be a spark. Remove power from the power tx, and check the audio transformer for continuity using an ohmmeter. Don't use an autoranging DMM. I had this work with audio transformers, and even with a Hallicrafters S-20R IF transformer that had an intermittent winding.

Of course, take precautions - at least follow the "one hand in your pocket" rule. Let us know if it helps.

Welcome from St. Marys, Ont. where there is 18" of snow and it's still falling.

Had two QSOs last night, both on 80. W2ICE/4 and John, N2BE. Bill had an R5 sig with John at R3. That was a struggle, but with repeats we made the exchange. Both agreed that it was a fun contact.

Starting at 1800R, I listened for G3QDQ on 40 for a half hour with nothing heard. Not surprising considering subsequent reports. At 6:30 QSYed to 80. Oh boy! AWA sigs...great. Got the TPTG tuned up...sounded FB. Here we go! At that point my usual S-7 RFI QRM jumped to S-9 + 5. Gave up. Later the QRM dropped to "only" S-8 so was able to copy Bill & John. Bill and John's were the only stns heard on 80.

To participate last night, I passed on two dinner party invitations. XYL's away so that would have been timely.

So far today worked on 40: N2BE, AA9DH, N3TE, W2LB and KB0MM. Condx fair to middling.

Will finish the Kelley day on 80.

73, Lou

P.s., N2BE ended our QSO with this: "Nice sig Lou for a TNT." What do you mean, "for", OM ?! ...Humph

Hi,
Nothing heard here today on 40 in Dorset either. Pretty much a repeat of yesterday. I have been calling on 7.055 from 20:30Z but nothing heard. I did hear what I thought was a qso in progress from an ac4ma? around 22:00Z tonight on 7.055, but readability and strength was very very poor. Band has been active with the Dutch naval contest most of the day, which ran same days as the Kelly party.

My 40 meter 171A Hartley rig seems to have lasted the duration but does need some work on the power supply. The transformer is running a bit too hot for my liking! Next project.

Not having used CW, I am having great fun honing my newly acquired skill and equipment. Looking forward to trying again on the next weekend

That was fun. I think I ended up with around 25 QSOs or so from this noisy hole in the ground, almost all on 80M. I had a near miss with KB0ROB on 40m and I heard several calls on 80M that I didn't work. (Don, VE3LYX: I heard you briefly on 80m Sunday afternoon, but the dishwasher went into rinse and wiped you out.) There's next weekend...

With the franken-forty-meter transmitter (see below) nearly built, I along with my eldest daughter changed the dipole on Saturday to add 40m legs. The new antenna meant there was a good amount of adjustment during the contest to correct for various transmitter pathologies. Sometimes T9, sometimes T7 (and I think that might have been a little generous a few times, but thanks for trying to be honest, guys). Anyway, it papered over the wobbulation and chirp a bit....

I've attached a side-shot of the transmitter table at K0SM with the room lit only by the tubes I had on the air this weekend. (Actually, the UV202 is at about half brightness, otherwise it washes out the camera). They are both shunt-fed Hartley's with center-tap keying. The 80m transmitter is in the back. It has sockets for two tubes in parallel but I just ran one and left the other socket open. The plate-blocking condenser and grid condenser are both homebrew from a February 1924 "Radio" article using copper and mica sheets in a bakelite sandwich. I had made a couple QSOs with them, but not run them at full voltage for hours on end. They survived the field test and I can breath a sigh of relief. This transmitter worked wonderfully.

Forty meters...yes...well...I'm still not getting the power out I should on 40M. Maybe its that old mercury condenser in the antenna or more likely the big transmitting micas I used to pad the 100pf tank variable (I missed by 500khz, and I wasn't about to wind another tank coil). I tried a few tubes and they're drawing approximately the right amount of plate current, but it's only about 5-10% efficient by the time it gets to the meter. I didn't notice anything hot that shouldn't be, but I didn't go poking around methodically. Maybe it's just the right coupling and tap positions which get trickier as you go up in frequency. Nonetheless, a few of you heard me for the little time I was there--thanks! I basically worked on the transmitter Sunday after lunch and worked a few people as I was tinkering. Originally I just wanted something so I could RF-test "jumbo socket" transmitting tubes, but on Friday I figured I might as well just build an RF oscillator with a 40 meter coil and give it the old college try. It's the NO3M-method of last-minute transmitter construction, and it turns out Eric's stuff both works and looks better. Maybe it's a practice thing....Anyway, the tube pictured is a relatively early (I think?) production UV-203-A, and most of the stuff around it was made sometime in the 1920's to 1940's. In the final analysis, it's a junkbox prototype that somehow found itself in a production environment. (This is a perfectly normal situation to me since my day job is software development.)

As built, it's was almost impossible to tune in all dimensions. Hopefully this will be in better working order next weekend!

It's the NO3M-method of last-minute transmitter construction, and it turns out Eric's stuff both works and looks better. Maybe it's a practice thing....Anyway, the tube pictured is a relatively early (I think?) production UV-203-A, and most of the stuff around it was made sometime in the 1920's to 1940's. In the final analysis, it's a junkbox prototype that somehow found itself in a production environment. (This is a perfectly normal situation to me since my day job is software development.)

As built, it's was almost impossible to tune in all dimensions. Hopefully this will be in better working order next weekend!

Andy K0SM/2

Hi Andy and TU for ur rpt.

I think I ended up with around 25 QSOs or so from this noisy hole in the ground, almost all on 80M.
25! I have about 7 on 80. The S-9 RFI QRM here is killing reception.

GN, Lou
Hot stuff...
Are you using the Faradon variable for the antenna loading?

Yes, the Faradon is in the series condenser in the antenna circuit. I think that's what R.C. said it was for, and with mercury rolling around in there it has to be a really poor tuning condenser! I think you mentioned this to me when I last visited. It would probably be even worse than the air variable I'm currently using on 40m w/o a vernier!
RCA advertised a similar shape condenser for a tuning with a different part number, but I don't know the technology having never seen one in person. This one is the UC-1831. Also this was back when anything below 200 meters was terra incognita, so you could get away with a little slop in the tank. "Low loss" and the real shortwaves were a couple years in the future! It wasn't tested at 7MHz, I'm sure of that!
We'll work next weekend, one way or another. I already know you can hear me with 50ma of antenna current on 40m at the right time. We just have to find each other.

Hello Andy - I think I got the answer to my question to Lou,VE3AWA regarding the tube I queried about from reading your post. FB on it being your tube, an early bg-pipped 03A. . ? I hope everyone in attendance had fun in the contest/operating event.

That was fun.?I think I ended up with around 25 QSOs or so?from this noisy hole in the ground, almost all on 80M.? I had a near miss with KB0ROB on 40m and I heard several?calls on 80M that I didn't work.? (Don, VE3LYX: I heard you briefly on?80m Sunday afternoon, but the dishwasher went into rinse and wiped you out.)? There's next weekend...

With the franken-forty-meter transmitter (see below) nearly built, I along with my eldest daughter changed the dipole on Saturday to add 40m legs.??The new antenna meant?there was a good amount of adjustment during the contest to correct for various transmitter pathologies.? Sometimes T9, sometimes T7 (and I think that might have been a little generous a few times, but thanks for trying to be honest, guys).? Anyway, it papered over the wobbulation and chirp a bit....

I've attached a side-shot of the transmitter table at K0SM?with the room lit only by the tubes I had on the air this weekend. (Actually, the UV202 is at about half brightness, otherwise it washes out the camera).? They are both shunt-fed Hartley's with?center-tap keying.?? The 80m transmitter is in the back.? It?has sockets for two tubes in parallel but I just ran one and left the other socket open.?? The?plate-blocking condenser and grid condenser are both homebrew from a February 1924?"Radio" article using copper and mica sheets in a bakelite sandwich.??I had made a couple QSOs with them, but not run them at full voltage for?hours on end.? They survived the field test and I can breath a sigh of relief.?; This transmitter worked wonderfully.

Forty meters...yes...well...I'm still not getting?the power?out I should on 40M.? Maybe its that old?mercury condenser in the antenna or more likely the big transmitting micas I used to pad the 100pf tank variable (I missed by 500khz, and I wasn't about to wind another tank coil).? I tried a few tubes and they're?drawing approximately the right amount of plate current, but it's only about 5-10% efficient by the time it gets to the meter.? I didn't notice anything hot that shouldn't be, but I didn't go poking around methodically. Maybe it's just the right coupling and tap positions which get trickier as you go up in frequency.?Nonetheless, a few of you heard me for the little time I was there--thanks!??I basically worked on the transmitter Sunday after lunch and worked a few people as I was tinkering.?;?Originally I?just wanted something so I could RF-test "jumbo socket" transmitting tubes, but on Friday I figured I might as well just build an RF oscillator with a 40 meter coil?and give it the old college try.? It's the NO3M-method of last-minute transmitter construction, and it turns out Eric's stuff?both works and looks better.? Maybe it's a practice thing....Anyway, the tube pictured is a relatively early (I think?)

production?UV-203-A, and most of the?stuff around it was made sometime in the 1920's to 1940's.? In the final analysis, it's a junkbox prototype that somehow found itself?in a production environment.? (This is a perfectly normal situation to me since my day job is software development.)

As built, it's was almost impossible to tune in all dimensions.??Hopefully this will be in better working order next weekend!

Joe,
I was trying to take a good picture of the 203 and 203-A next to each other, but I can't get the lighting right. The one in the transmitter picture is a UV-203-A. If the base doesn't tell you, you can tell because of the big metal plates and scaffolding. In fact, the 03-A appears to be identicall to the UV-211, except there is more grid wire the spacing might be different to give the higher Mu. (My only UV-211 is a display with a hole in the plate, which I would have loved to have been a fly on the wall to see. Anyway, it probably shouldn't be the basis of any scientific comparisons). The one in the picture is at near full brightness, as it has a thoriated filament. I'm not too scared lighting it, as the lower filament current means its more likely to loose emission before the filament goes (this was the big improvement of the -A, much the way the UX-210 was a big improvement over the UV-202). The older UV-203 (discontinued in 1923, I think) has a pure tungsten filament, and is bright white like the UV-202 when lit...only brighter (the 202 is what you correctly identified in the back of the picture). It has a thinner plate that looks essentially like a UV-201 or UV-202, only bigger in area. I guess GE was also playing with the base material as I've seen them with both the familiar ceramic base and a dark material that looks like mica. My guess is that when people started putting more than a KV between the plate and filament they had issues. I think I read that Fred Schnell even took the bases off for some of the early transatlantic tests to avoid HV arcs in the base when the tubes were overloaded. I'm not sure of the history of the base material, but I'd be interested if anyone knows. (Tyne's book is coming for Christmas, which I really need now).
I've never seen an old UV204 (non -A), let alone one lit up, but I bet it was something you didn't want to be too close to. 14.75A at 12V on a pure tungsten filament is a 177W light bulb. That's more than my garage light, and another reason to keep the transmitter over in the corner of the room or in a separate building.
I'm guessing quality control in tube was steadily improving since the early 20's. I can see a 95 year old fingerprint, presumably of a GE factory worker from ages past, on the brass collar inside of one of these. It's a little reminder of where process control was then.

Hello Andy,
? ? ? ? ? ? ? ? ? Many thanks for the information you gave me about the tubes in question. Yes, the plate area on the 03A was somewhat larger than a standard 03, the original "fifty-watter". I can research this myself, but was wondering if you know offhand if the UV-203A had a higher plate dissapation than the standard UV-203? FWIW, whilst on the subject of the 203, the "Taylor" company came out with their own high performance variant of it sometime around 1937 designated the "HD203" or HD203A", I forget which one but probably the latter, and would have to take a look at the one I have. Moving along about the HD203, the Taylor HD tube sported a graphite anode and consequently a high plate dissipation than it's 203 variant cousins. There may have been other refinements in the HD tube as well. Taylor also made a 203A that I believe also used a graphite anode as well. One selling point about the HD203A was that it was more or less a drop in replacement for the UV-203 or 203A.?

Regarding the UV-204, the original non-A designate was a copy of the famous "P" valve introduced very late in WWI. It too was rated as being able to develop 250W output, which was quite a feat in 1918! It remained basically unchanged until around 1923 when the UV-204A was introduced.The original "04" like the "P" valve had a round cylindrical shape in the middle of it housing the plate and it's supporting apparatus. The UV-204A was different. Instead of the familiar round shape in the middle of the glass envelope; it now had a elongated shape to it. The output of the new "04A" remained the same.

Somewhere in my collection of "iron" I believe I have a proper filament transformer for a UV-204A. If I can locate it, I'll see if I can take a few pictures of a original round shaped envelope "UV-204" with it's filament lit at full intensity to send to you and others in the AWA ?Group reflector. I lit it off only once some ten years ago or so, and remember that it did have filamentry continuity and was quite bright. As you previously stated, it's a big 177 watt light bulb!

I hope you and everyone who is participating is having a HI HI FBOM time in the B Kelly Contest. Tell Lou he hasn';t heard my warbling "peanut whistle" signal on the air since my CW skills are in need of a lot of practice, and as a result are painfully slow. Maybe next year or if the US ever opens up the 600 Meter band for Amateur Ops even sooner since it'll force me to practice again.?

Very best regards,
Joe Cro N3IBX

Now Larry, I did not only operate on 3608. That is just where I choose to start(aka in the clear). I asked a couple of times where folks were as you can see. Never got an answer. However I did not come up dry. Many ops are from this group are above 7100 which BTW is also not in the recommended spot. Anyway best results I had were with my Ancient German tubed rig. Also my old first built TNT which now has a 10 tube had success on 40M. My new Hartley came up dry. I had a couple of answers with it late yesterday on 80M but they got run over in the noise and i was unable to pick them out again.
Still, twas fun. Filament batteries in the German tubed rig did not ever become a problem. I am surprised as I used it a lot.

OK, Don; I understand. Sounds like you had fun, which is the important thing. Still wondering why I didn't hear you on either 80M or 40M, as I was listening quite a bit for stations I hadn't worked yet on both bands.

For the past several years 40M BK ops have been concentrated in the 7100 - 7120 KHz range because it tends to be less crowded than lower in the band. The "official" info at http://www.antiquewireless.org/bruce-kelley-memorial-cw-qso-party.html now has the recommended frequency range for 40M at 7100 - 7125 KHz.

Hope to work you on both bands next weekend.

73,
-Larry/NE1S

I had both 211 rigs (40M Hartley and 40m TNT)on sat night after midnite as they fit the power spec with the low plate voltage I run. I have made a pond hop with the hartley so figured it was the right weapon again but I didn't get even one response. Hopefully next weekend results will improve late night. Stayed up as long as I could. Actually lately early morning on 80m is very good. Much better then late day is. If that remains so we shall see. of course if no one is on it means diddly squat.

?Hello All,
? ? ? ? ? ? ? ?I am deeply saddened by the passing of Gordon Kittel, W3GK yesterday afternoon. Gordon was a good friend of mine and a great person to know. He was not a "AWA" member, but known by many AWA members in the Philadelphia Pa. tri-state area as a previous Amateur Radio equipment dealer from his previous stores he had in Pennsylvania and through his attendance at just about every "Hamfest" and major Amateur Radio event in the area for a long period of time.?

Gordon enjoyed operating and working on vintage equipment, especially receivers; and had a keen technical knowledge of them. Through his sixty some years experience as a Amateur Radio Operator and retail radio store owner and collector, there was hardly a radio made in the past sixty years or so that he either didn't have experience with working on, or having owned and used on the air. He was a terrific person and will be missed by all who knew him.?

Funeral arrangements are to be determined by his wife Carol, and son and daughter Steve and Ann. Please keep Gordon and his family in your prayers.

With deep regret,

14603. 2016 BK First Half Postmortem de W2ICE/4

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-12 13:58:18 UTC
From: Bill Stewart
Topic: 14603 Message: 14603

GM All,
The BK got off to a slow start here on 40 mtrs. After an hour of calling I only worked NE1S and WA9WFA. I moved to 80 mtrs around 7PM and it was on for the rest of the night....'till around 1AM. I went to 160 mtrs at 8 & 10 PM and Midnight. I worked 3 stns on 160: W8CDX - didn't realize that was NO3M and wondered where Eric(NO3M) was...duh; NW2K, Dean & N4GJV, Ron. I was hoping there would have been a few more that would make it into NC. And of course, the highlight was working Tom, DJ5RE, on 80 mtrs. That was my first time across the pond with a 1920s rig. I heard Tom later, after the W2ICE/4 contact and called him using my own call sign and we worked again. Hats off to Tom for a super op and station. I didn't get up too early Sunday morning, so only worked two stns on 80 mtrs and then back to 40 mtrs. That band worked well up 'till I went back to 160 mtrs (5PM) with no BK contacts. I finished out on 80 mtrs. I worked first-time BKer, Jim, KK4GFR. on 40 mtrs....I hope the bug has bitten Jim severely and we will be hearing from KY in future BK events. I think I heard at least one W7 stn (think it was on 40), but could not make out the call. If you guys out west read this, please comment on when you think 40/80 mtr condx would support a contact. It seemed to me that there was a brick wall from west of MN, KY and on down.....just barely a peep from there to the west. Sure missed, Steve, VE7SL. The totals for the first half are: 160 mtrs-3; 80 mtrs-26; 40 mtrs-20; a grand total of 49 AWA contacts.

As usual, I heard many unique notes...all music to my ears. Thankfully, the rigs here worked flawlessly....and even seemed that the Hartley got to sounding better, on 40mtrs, the more I used it. On 80, to my ears, it sounded pretty good. During this half, I got no cat calls, no 'lid' comments and no one told me my battery was low.....hi. So guys, I guess its back to doing some more tweaking this week. Trust we will have good condx for next weekend. Many thanks for all the contacts and my thanks to the AWA and BK crew for letting me use W2ICE/4 in this years event.

73 de Bill W2ICE/4 - K4JYS

Yes I was surprised too. Usually we connect somewhere in the frey. I never even heard you. Nor Lou which is unusual. Anyway I put the toys away till next weekend. Sori you couldnt hear me this morning. I was just doing a barefoot signal check with Dave as I had a powersupply go south.(bad hum) I tore it apart and completley rebuilt it with a different design. I could have plugged in the amp but then I wouldn't know which was the cause. Anyway apparently it is OK now. I could hear you though, and Tim, although not strong. Anyway till next weekend. Glad Bill and Tom worked. Must have brought a few grins!donVe3LYX

> Now Larry, I did not only operate on 3608. That is just where I choose to start(aka in the clear). I asked a couple of times where folks were as you can see. Never got an answer. However I did not come up dry. Many ops are from this group are above 7100 which BTW is also not in the recommended spot. Anyway best results I had were with my Ancient German tubed rig. Also my old first built TNT which now has a 10 tube had success on 40M. My new Hartley came up dry. I had a couple of answers with it late yesterday on 80M but they got run over in the noise and i was unable to pick them out again.
> Still, twas fun. Filament batteries in the German tubed rig did not ever become a problem. I am surprised as I used it a lot.
> donVe3LYX
> OK, Don; I understand. Sounds like you had fun, which is the important thing. Still wondering why I didn't hear you on either 80M or 40M, as I was listening quite a bit for stations I hadn't worked yet on both bands.
>
> For the past several years 40M BK ops have been concentrated in the 7100 - 7120 KHz range because it tends to be less crowded than lower in the band. The "official" info at http://www.antiquewireless.org/bruce-kelley-memorial-cw-qso-party.html now has the recommended frequency range for 40M at 7100 - 7125 KHz.

Good time on 40 yesterday afternoon with my thundering 0.75 watts out into a G5RV.

Lou, you had a 559 into CT but I could not raise you. I seemed to have a pipeline into Maine as I had 3 contacts up there.

Look forward to next week.

□

Hi Andy and TU for ur rpt.

I think I ended up with around 25 QSOs or so from this noisy hole in the ground, almost all on 80M.

25! I have about 7 on 80. The S-9 RFI QRM here is killing reception.

GN, Lou

Hot stuff...

Are you using the Faradon variable for the antenna loading?

Good Morning all, Last weekend was fun for me ! I only worked 3 contacts but had much fun! Two on 40 and one on 80. Mn,Pa,NC. I was able to work Bill W2ICE/4. Got to experience wind modulation, as it was quite breezy here. My shack is in a cellar, so I operated for a while and warmed up for a while. I have many questions as to what most folks are using for 160m antennas. Next year I hope to have a couple of 27's in parallel. Maybe the coming weekend will be a little warmer. 73 Jim kk4gfr

Re: 160M antennas

If your target audience is within a 500-600 mi radius, a low (even 100ft is low on 160 for horizontal antennas) dipole works well. Beyond that, some kind of vertical is preferable and there are many variations besides a full sized vertical: Marconi "Tee", Inverted-L, top loaded monopole, etc. A good counterpoise (ie radials) is required to keep efficiency high, either on/in ground or raised radials. There is a "folded" counterpoise that some have used in space limited installations developed by K2AV.

Deciding what antenna to install generally depends on 1) your target audience and 2) space available (of course, money and other things factor in)

The old Handbooks illustrated just a long wire (~120 ft by the old tables) straight to one end of the antenna coupling coil on the transmitter, put a tuning cap in series with the other end of the antenna coil and ground. Basically a base loaded semi-vertical, almost inverted-L... but it's probably best to use a transmission line and keep the current node outside of the shack!

Hi Jim,
Glad you had fun. In my first BK, I made a few contacts and was hooked. Still having BK fun after 15 or so events. I have a pretty nice 'Studio B' but lacks some good heat....the Chinese infer-red heater just don't do the job, so operated at 60 degrees and in insulated coveralls & toboggan ....hi. Was ok 'cept for my feet.

Eric passed along some great info on the 160 mtr antenna. Here, the TB antenna is a simple inverted L with a four wire counterpoise. I have worked around the country, into the Pac. a couple of times, EU and the Carib. too with 100 watts. And with the '24 Meissner have worked Eric, Lou, Dean and generally from Fla to VE3 at abt 2-3 watts output. The antenna is generally canopied with near 100 ft pines, so far from ideal. If you have some way to get a, oh 50-60ft vert. wire and room for the horiz, and don't mind four wires at abt 10 ft high running across the yard, this might be worth considering. Of course this is not scientific...just my experience. I have worked a number of stns using simple TB antennas....one was a stn in Fla using a magnetic loop in his bedroom and was quite copy-able. Oh, worked a guy not long ago using a helically wound vert...so there are a lot of choices. Let us know what ya got to hang something on.

Hope to work you on 80 next weekend...73 de Bill K4JYS

Hello Bill, My antenna is an end fed sloping 108' piece of wire with a 9:1 unun. I use a mfj tuner. 40 & 20 tune well. 80 not as good. To be honest, I don't even know if it would tune 160. My receiver is an Allied a-2516. I would have to wind a coil for my regen to listen to 160. Always wanted to try TB though. Jim

Jim,
I had decent success last year in the Stu Perry contest running QRP from /VE3 (and thus in the same power output class as the BK). I just brought a 100ft length of RG-8X, a balun, and lots of THHN from Home Depot. I made in the field essentially what Bill has-- an inverted L. (Mine was a bit long--probably 160ft with only about 45 feet of it vertical) with a four 1/4-wl radials just rolled out on the ground/snow. If you only have a few radials its best they be tuned. You are probably better off burying them or elevating them, but that's often not an option (especially at my in-laws place!). It's 160M, so if you don't have a matching network at the feedpoint to give you 50 ohms on the radio end you can probably get by with a tuner in the shack. That's what I did. Coax losses aren't going to be a show stopper, and pretty much everything is a compromise at 1.8 MHz for us mere mortals. The feedpoint impedance of a good inverted L is below 20 ohms.
In fact, as you add radials you should see the feedpoint SWR (in a 50 ohm world) go *up* as you add radials (reducing ground resistance lowers impedance). The "phantom antenna" that that the Hartford ARC used in 1921 for their transmitter competition was a 12 ohm load, which gives you an idea of what antennas were like then--lot unlike a good inverted L, which is indeed what people used then. Power being equal, Ohm's Law says you can get lots antenna current a 12 ohm vs. 50 ohm antenna--more than an amp from a UV202 in that competition, which you'll never come close to with a 50 ohm antenna with a "5W" tube. In general, adding more counterpoise and radials would keep lowering the impedance of the antenna by reducing ground loss, and you could get well under 10 ohms with a good system. The tubes could match this low impedance, and you would see more antenna current the more efficient your aerial was. In the minds of many back then, "more counterpoise = more antenna current = louder".
Interestingly, hams confusing antenna current with power output was a stumbling block that prevented people from moving much above 200 meters in the early 20's. I suspect that when they tuned higher their antenna had a higher characteristic impedance due to the inductive reactance of the now electrically long wire, even though the ground losses probably went down at the higher frequency. The antenna was likely more efficient up there (when matched), but they weren't able to get as much current as they could on the lower frequencies because impedance of the system was higher. Several people were surprised when all of the sudden they could work coast to coast up at 170 meters with 1/3 the antenna current. When the shortwave bands became a "thing" in 1924, the QST editors were pointing this out often.
Andy K0SM/2

Hi Jim,

Several years ago I was in QSO with Joe, N3IBX on 160 using my ladderline fed 80 metre dipole with ATU/balun. Joe could hear me. In a rush, using the ATU, I loaded the feed line as an endfed. Joe's reaction to my increased signal strength was ecstatic. Yet, my "vertical" made for a poor RX aerial. Moral of this story: First play around with what you have.

Jim, what are your operating plans for this weekend? Here, I will concentrate on working Ian, G3ZDQ on 40 for the first 1/2 hour. After Ian and I work 599 both ways I will see what's up on 40 then down to 80 for the rest of the night.

Hoping to work you and a stn with a thundering 0.75 watts out into a G5RV.

73, Lou

The UC-1819 was the one advertised for receiving use (100PF to 5000pf!). It looks like its also a mercury condenser, though, just different capacity range. Both this and the UC-1831 are advertised in a full page add in January 1921 QST, p. 107 (available on Google books). A full page for a condenser....RCA wasn't hurting for money then!
Yes, a UC-1831 gives "more antenna current for the average station."
Andy K0SM/2

The UC-1819 was the one advertised for receiving use (100PF to 5000pf!). It looks like its also a mercury condenser, though, just different capacity range. Both this and the UC-1831 are advertised in a full page add in January 1921 QST, p. 107 (available on Google books). A full page for a condenser....RCA wasn't hurting for money then!

Yes, a UC-1831 gives "more antenna current for the average station."

Andy K0SM/2

On Sunday, December 11, 2016 10:37 PM, "'Louis Vermond' ve3awa@... [AWAGroup]" <AWAGroup@yahoogroups.com> wrote:

RCA advertised a similar shape condenser for a tuning with a different part number.... The receiver version? What was it's part number, Mike?

... series condenser in the antenna circuit. I think that's what R.C. said it was for, and with mercury rolling around in there it has to be a really poor tuning condenser!
I tried using one as a tank shunt condenser. Key down, the TNT's output pulsed.

We'll work next weekend, one way or another. I already know you can hear me with 50ma of antenna current on 40m at the right time. We just have to find each other.
YUP!

Bill - had a brief chance to listen just after the start at around 3:15 my
local time yesterday afternoon...you had a nice workable signal up here on
40m CW at that time.

Spurred into activity by the joy of Bk particpation I dragged the no vaccum triode off the shelf and went to work. Doug, you asked me a very long time ago to measure something next time I tried it so if you remember what it was I will. Coil and soup can lid variable tunes down to 4.3 mcs so I may have to add a few turns to get it into 80M. paer gridleak is currently around 8 megohms which is high but still should oscillate. Underneath is a fixed soupcan lid capacitor probably somewhere between 100 and 200 pf. Choke is wound on a ham bone section. It will either work or it won't . I gotta try. I know even if I get it going it wont be Bk legal but it will be fun.

yes 6:00 PM ur time...sigs to ur direction from here on 40m are usually good for at least another 3 hours but by then most of you guys have long gone to 80m. We're usually lucky to get an hour in at the contest start before everyone is gone, even though prop is still good....but I can see the problem from ur end as there is not much to work back here so much wiser to QSY!

I started out on 40M, found Bill right away and worked him. I heard Bill work WA9WFA, so gave him some calls slightly north of Bill's frequency; no joy. Then I called and called with no responses, eventually a non-BK participant called me and we chatted for a bit. Back to calling with no responses. After an hour I realized I wasn't having much fun so moved up to 80M and made lotsa QSOs ;-)

Joe,
Trying to get caught up here....
The base of the UV-203-A I have here has the "50 WATT" label on the base and the newer (post-1923) RCA logo. Whether or not it actually could handle 100W dissipation I don't know. I'm not going to find out :-) It also lacks the white logos on the glass (maybe it came with a sticker?). Other than that its the same envelope and base (the license is inked on the back of the base just like we see on some of smaller brass based tubes.) It was marketed as a 50W tube, but at some point it went to a carbon plate, and a slightly fatter bottle.
I attached a picture of a UV-203, UV-203-A, and a "modern" 203A, all my by RCA side by side. I know you've seen these Joe and probably a hundred variations, but it might be of interest to others. Looking around online I see that these brass tube bases sometimes become so oxidized that the ink labels are gone (or maybe someone "cleaned" them). Often you can tell what it is (or was) by knowing the construction.
Andy K0SM/2

On Monday, December 12, 2016 1:57 AM, "N3IBX N3IBX@... [AWAGroup]" <AWAGroup@yahoogroups.com> wrote:

  Hello Andy,   Many thanks for the information you gave me about the tubes in question. Yes, the plate area on the 03A was somewhat larger than a standard 03, the original "fifty-watter". I can research this myself, but was wondering if you know offhand if the UV-203A had a higher plate dissapation than the standard UV-203? FWIW, whilst on the subject of the 203, the "Taylor" company came out with their own high performance variant of it sometime around 1937 designated the "HD203" or HD203A", I forget which one but probably the latter, and would have to take a look at the one I have. Moving along about the HD203, the Taylor HD tube sported a graphite anode and consequently a high plate dissipation than it's 203 variant cousins. There may have been other refinements in the HD tube as well. Taylor also made a 203A that I believe also used a graphite anode as well. One selling point about the HD203A was that it was more or less a drop in replacement for the UV-203 or 203A.
Regarding the UV-204, the original non-A designate was a copy of the famous "P" valve introduced very late in WWI. It too was rated as being able to develop 250W output, which was quite a feat in 1918! It remained basically unchanged until around 1923 when the UV-204A was introduced.The original "04" like the "P" valve had a round cylindrical shape in the middle of it housing the plate and it's supporting apparatus. The UV-204A was different. Instead of the familiar round shape in the middle of the glass envelope; it now had a elongated shape to it. The output of the new "04A" remained the same.
Somewhere in my collection of "iron" I believe I have a proper filament transformer for a UV-204A. If I can locate it, I'll see if I can take a few pictures of a original round shaped envelope "UV-204" with it's filament lit at full intensity to send to you and others in the AWA Group reflector. I lit it off only once some ten years ago or so, and remember that it did have filamentry continuity and was quite bright. As you previously stated, it's a big 177 watt light bulb!

I hope you and everyone who is participating is having a HI HI FBOM time in the B Kelly Contest. Tell Lou he hasn';t heard my warbling "peanut whistle" signal on the air since my CW skills are in need of a lot of practice, and as a result are painfully slow. Maybe next year or if the US ever opens up the 600 Meter band for Amateur Ops even sooner since it'll force me to practice again.
Very best regards,Joe Cro N3IBX On 12/11/16, 'aflowers@...' aflowers@... [AWAGroup]<AWAGroup@yahoogroups.com> wrote: Joe,
I was trying to take a good picture of the 203 and 203-A next to each other, but I can't get the lighting right. The one in the transmitter picture is a UV-203-A. If the base doesn't tell you, you can tell because of the big metal plates and scaffolding. In fact, the 03-A appears to be identicall to the UV-211, except there is more grid wire the spacing might be different to give the higher Mu. (My only UV-211 is a display with a hole in the plate, which I would have loved to have been a fly on the wall to see. Anyway, it probably shouldn't be the basis of any scientific comparisons). The one in the picture is at near full brightness, as it has a thoriated filament. I'm not too scared lighting it, as the lower filament current means its more likely to loose emission before the filament goes (this was the big improvement of the -A, much the way the UX-210 was a big improvement over the UV-202). The older UV-203 (discontinued in 1923, I think) has a pure tungsten filament, and is bright white like the UV-202 when lit...only brighter (the 202 is what you correctly identified in the back of the picture). It has a thinner plate that looks essentially like a UV-201 or UV-202, only bigger in area. I guess GE was also playing with the base material as I've seen them with both the familiar ceramic base and a dark material that looks like mica. My guess is that when people started putting more than a KV between the plate and filament they had issues. I think I read that Fred Schnell even took the bases off for some of the early transatlantic tests to avoid HV arcs in the base when the tubes were overloaded. I'm not sure of the history of the base material, but I'd be interested if anyone knows. (Tyne's book is coming for Christmas, which I really need now).
I've never seen an old UV204 (non -A), let alone one lit up, but I bet it was something you didn't want to be too close to. 14.75A at 12V on a pure tungsten filament is a 177W light bulb. That's more than my garage light, and another reason to keep the transmitter over in the corner of the room or in a separate building.
I'm guessing quality control in tube was steadily improving since the early 20's. I can see a 95 year old fingerprint, presumably of a GE factory worker from ages past, on the brass collar inside of one of these. It's a little reminder of where process control was then.

On Mon, Dec 5, 2016 at 3:07 PM, Larry Szendrei <ne1s@...> wrote:
Hello,

As some of you may know*, over the past 3 weeks or so I've been building a mid-1930s superhet communications receiver. It's been on "the list" for a few years now, but for whatever reason it suddenly became the most appealing project on the list, so I decided to "strike while the iron was hot" and get busy.

Topology is as follows - Jones "Super-Gainer" front-end with a type 57 regenerative mixer and 56 oscillator, two IF stages with AVC at 455 KHz using 58s, a 2B7 diode detector and 1st audio, 56 split-load phase inverter, PP 59s in the audio output, 5Z3 rectifier, and 24A BFO using the Dynatron circuit. 10 tubes in all. I am building it on the carcass of a "Columbia SG-8," which was a TRF AM broadcast set from 1929. It was my grandfather's, he had picked up the chassis and matching electrodynamic speaker on Radio Row in NYC in the 1930s. He had torn it apart and it was the foundation for many projects by him, and then me, as far back as I can remember but has been neglected as an almost bare chassis for the past 40 years or so. The only parts I am using that are original to that set are the chassis, power transformer, filter choke, and the speaker which still works and sounds

great.

About two weeks ago I had completed and was testing the front end only, using an external power supply and feeding the mixer output into a BC-453 tuned to 455 KHz. Last Tuesday and Wednesday I finished it up to the ("2nd") detector and was feeding its output into an external audio amp. It worked extremely well (about as well as any communications receiver of that era that I own, and I own a few), and I used it in a QSO with W2PFY on 40M AM. So far I have only wound coils for 40M. Actually they go from 40M to almost 20M; with a little tweaking of the coils I think I'll be able to get them to cover both bands. Eventually I'll wind sets to cover at least 160M and 80M as well.

As of this morning the power supply and audio sections are just about done, and the BFO will be the last section to complete - not counting a front panel. A Pilot drum dial will replace the large pointer knob on the bandspread tuning condenser. I am waiting to install it last to reduce the possibility of damage to it. The 2 under-chassis photos show the progress that has been made in the past week - actually a little less than that.

*it's about all I've been talking about on the air recently

73,
-Larry/NE1S

I have an electronic copy of the Stancor catalog #S-106. Lots of P-**** numbers in there, but this catalog jumps from P-1834-3 all the way to P-3020.

No joy...

Subject: [AWA Group] Part Number Info needed

  Gentlemen, Once again I find myself looking for part number information. I was recently given a power transformer that is in reasonable condition. A couple of the leads needed replacement. Electrically, it is FB. The giver allowed as to it coming from a Johnson Ranger 1. Unfortunately, the part number does not match the nomenclature shown in the parts list for either a Ranger 1 or 2; Navigator; Viking 1 or 2.

The part number is clearly stamped into the end bell and on the paper winding cover: P2534.

Can anyone help with IDing this beauty? I would be obliged for any help.

Roger/K1TG _

There were three versions of the Ranger.

Only the third version had the transformer with a tap for a bias supply.

There were two versions of the 'porch' behind the Function switch that had several 2W resistors to drop the high voltage, and the second which did not have those resistors.

That's not a Stancor number, rather a Johnson part number.

Hi all,

Here is a photo of the home made straight key I use for the Bruce Kelley. There's a lot of current in the center tap line so I made some silver contacts for it and have been happy with the results. I seldom have to clean the contacts during the event. Hopefully I will hear some of you on 160 meters after the embers burn down on 80 Saturday night...

Don,

The base was machined from a solid cylindrical chunk of mild steel. I used both a lathe and a milling machine to get the required shape. I generated a lot of chips but the end product made it worth while. The piece I started with was solid and three inches in diameter and an inch thick and whittled on down from there mostly on a milling machine.

Good morning all, I found that if I pad my tank on the Hartley with 1060pf, I'm in the 160 meter band. The station receiver is an Allied a-2516 (no 160). So I wound a 160 coil for the regen. Now this poses another problem, spotting the transmitter. I have a hand held freq. counter and gdo. That would probably get me spotted but no way to monitor my signal. Any ideas? Jim kk4gfr

Yeah - build a "growler."

Or, if you have an old frequency meter like a BC-221 or LM series, you can both monitor your own signal plus set your receiver on the same frequency as your transmitter (or vice-versa). You may even be able to use it as a direct-conversion receiver, or as a heterodyne oscillator so you don't have to operate your regen in oscillation. The possibilities are endless!

Hello Jim,
? ? ? ? ? ? ? ?Somewhere on the internet may be plans for a relatively simple rx converter with a 7.0mhz IF to go from 40M to the 160M band. Just a idea.
I have said converter built by someone else. It is all transistorized and works very well. I was told the plans for it are on the internet somewhere when I acquired it some 15+ years ago. I never found them, but haven't searched for them in a long time. Possibly by now they are out there.?

I use my 160M converter with a HB superhet that only covers 20M and 40M. It works very well on the 160M band when I have the converter inline with it.

If I find any information on it I'll forward it to you. Even though I have a converter, I'd like to have more information about it.

Very best regards,
Joe Cro N3IBX

Thankyou Joe. Probably the best long term solution. My gdo has a headphone jack. An old Millen. I have never used headphones with it but if I can monitor note with it, I'd feel confident to put the rig on the air. I set the tap by watching plate current but that's no substitute for hearing it! I'd love to make a BK 160 meter contact! 73 Jim

Subject: [AWA Group] 160 meters

Good morning all, I found that if I pad my tank on the Hartley with 1060pf, I'm in the 160 meter band. The station receiver is an Allied a-2516 (no 160). So I wound a 160 coil for the regen. Now this poses another problem, spotting the transmitter. I have a hand held freq. counter and gdo. That would probably get me spotted but no way to monitor my signal. Any ideas? Jim kk4gfr

Hello Bill, I listened to my transmitter with Millen gdo. Sounded pretty good. Then spotted regen with same gdo. I will try listening for second harmonic with Allied. Suppose to get real cold so won't be in the shack for a couple of days. I found a schematic for a rf actuated cw monitor using a 555 chip and handful of parts. Be mighty handy for us regen guys. Bummer about the 160 cw contest! I'll be trying anyway. 73 Jim

I have wantd for sometime to do a broadcast band to 160M conversion with an old ac/dc or what southerners call an AA5. I now know thanks to Jim how to get a bfo in a matter of a few minutes on a tube sperhet. I mad a deal for a set with octal tubes when I fixed four radios for a fellow but he promptly forgot it once he had them all going. However I haven't and te next one I come across is going to have it happen. In fact turning one of those into a complete low power station would not be difficult. However an easy didicated receiver would require little more then a slight retune and If fudge for BFO I think. Just to try would be fun.

Hello Don, Sounds like a fun idea. Just wanted to let you and others know of a neat little transformer. The Triad N-68X isolation transformer. It is 50VA and can be wired for 110 or 220V. Stout enough for many homebrew projects and they are reasonable. Just have to run a separate filament transformer. What is qrp on 160? 5 or 50 watts. Would like to get my feet wet there. 73 Jim

Have only ever logged one qso on 160M, That was with one of my ARC5s. My collins station does 160m but I haven't had it there yet except for some SWL ing with the TCS13 rx.. Content to get it running well on 80M so it will be new territory for me as well. I have no qualms with AC DC set ups.however that might make a good mod transformer.

While operating the 1929 BK Sunday afternoon I made an interesting discovery on how to fine tune the transmitter frequency. I set down a can of carbonated water about 12” from the Colpitts copper tubing coil. The frequency promptly changed several hundred Hertz. As I moved the can closer like from 12” to 10” and the frequency continued to drop. I would pull the can away and the frequency would increase.

SO now when you listen to my silky smooth frequency adjustment, you can visualize me just grabbing the can and moving it closer or further away.

I’ll bet it works even better with a can of beer :)

Be careful of some of the metal beer mugs, the alloy used can contain lead! I suppose a stein mightwork if it has a metal lid. Of course if you were to find a vintage steel can the effect might be moreprofound.
I wonder if the orientation of the beer can would matter?

This obviously calls for extensive and careful testing.

Is it impacted by:

· The ABV?

· The amount of hops?

· The addition of other flavorings?

· The type of container?

· The diameter vs height?

· Impact of air pressure

One cannot simply presume on science…..

No, I have to exercise some self discipline. I have several now. Some really ancient too. BTW there was also an unknown NOS tube with a round ball style glass. 4 pin and a cap so it wouldn't be a rectifier I would think. At $35 when I looked it would have been a bargin and still may be. It was compared in size to a glass coke bottle.
Since getting the Collins station here and now on the air I am somewhat content. I am hoping to log more contacts this weekend in the BK then last. Will probably concentrate on 80M with my new Hartley. Gave away two old radios lately. Both working. Need to sell a few too. My DX60 station and my Trio 59R rx I think as well as a HP Nixie tubed FreqCounter and a HP DB meter would not be missed here. And then just keep what I like and use.

Hello,

I devoted much of yesterday to fine tuning the TNT for 40 mtrs. The 40 metre tank coil I had was built in a rush several years ago and looked like it. That has changed. Also, brought the grid coil resonance to just below 7 megs where it is supposed to be for efficient bottom end operation. I am pleased with the signal quality results. At 10Ws input, the output is 3.5Ws.

If anyone wishes a 40 and /or 80 mtr. test report this evening starting at 02:00GMT, please let me know.

73, Lou
VE3AWA

At the specified 5 turns, the tank circuit would not tune below 7100kc.
With 6 Ts, the shunt capacity at the bottom of the band is 440mmfd. Hi-ish C.

Beautiful work as always Lou!

I like your 40m tank coil. Mine as you can see is 5 turns but bunched up with the tube bent 90 degrees on what would be the operator facing end to make it fit the beehive spacing. At least one of the old TNT articles must have shown it this way (don't have any of them handy just now). Yours looks nicer.

73,

Hi. What is the spacing between turns on your tank coil and how did you determine the resonance point of the grid coil? I had the crazy idea to sweep mine (grid coil, in circuit) with the grid dip meter while powered off, found a dip at ~9 megs. Added as many more turns as would fit on my form which gave me a total of ~ 37. Checked it again with the grid dip meter and found the dip now at ~7 megs. Powered it up but found that the plate current was lowest with the cap fully meshed, ~6.7 megs. Started removing turns expecting to see the dip in plate current moving upwards but instead it just became steady. By that I mean the current would change only a very small amount over the turning range. Kept on removing turns and the plate current dip returned but now the dip was in the 40 meter band. The tone at this point was very good with very little chirp but power output had dropped to about 1W. As the coupling of the antenna and plate coils is increased I reach a point where the power peeks and starts to fall again. Twenty-three turns remained. If I keyed the transmitter with the cap fully meshed it would not oscillate at all, had to have it tuned higher to get it to fly. I put one turn back on it for the BK. Power out ~ 2W. All very interesting but I'm not sure what it means. 3.5Ws would be great but I am not there yet;-(

73,

James/KB7LJP

PS I did make one BK contact last weekend so all was not lost. I think the times I was on were not the best for 40, will mix that up some this week.

Got up early this morning. After morning vespers fired up the Collins TCS rigs for some Old Mil Radio Net ativity. Got a decent sig report as faraway as Florida so i wont even breath on It. After I finished with the group I cleared the bench and set up the new hartley with a 45 tube installed. Tuned it up on 3570 and left everything ready to go for tonite. I have to play fiddle but should be home before 9 Pm est so I can just throw the switch and go. If this morning's AM activity is any indication the bands should be good tonite. After midnite I will run the monster Hartley. That should make it across the pond as well so I will start around 7035 and 7052 then move on to 7100 to 7125 till I get too sleepy to operate. My goal though is to log a few with the new Hartley on 80M. Didnt get enouf last week to be in the hunt so I am just in for the fun and to help out others fill their log. Fun is the only reason I play anyway.

Hello James,

My e-mail server has been down hence the late reply.

What is the spacing between turns on your tank coil .... 1/2"

and how did you determine the resonance point of the grid coil? As you did. Removed excessive turns until the plate I was at lowest point at desired frequency. I was not confronted with those results.

PS I did make one BK contact last weekend so all was not lost. There are a few VE3s that will be looking for you tonight.

3.5Ws would be great but I am not there yet... I am using a 210 with 350B+. I could easily achieve 6Ws out, but signal quality (quality here refering to purity of tone, drift and chirp) degrades. As we all know, light antenna loading it the magic fix.

All very interesting but I'm not sure what it means. Yes, and I'm not sure either. There are others here who do I'm sure. Well "others"?

GL es CUL James, Lou VE3AWA

Howdy James, This may not have any bearing on the problem you describe but I would be leery of that tiny pie-wound choke.If it is iron/ferrite cored it can and will do strange things. There was an article in ER re: the little beasties. Ifmemory serves it was written by W7EKB. I am mentioned in the article for having a problem with a Q-Multiplier I built. I stuck an old-fashioned 2.5 mH choke in the circuit and Presto! Chango! it even worked. Roger/K1TG

Need two of these REL coil clips. Please look in your junk boxes. With them
I can proceed with project.

TKS, Lou

Hi. Had another option for an RF choke so gave it a try but it made things worse so put the old one back in for now but will look into that more after the BK.

Thank you and 73,

James/KB7LJP

14705. Any BK 160m? Fourth try to post

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-17 19:52:26 UTC
From: Bill Stewart
Topic: 14705 Message: 14705

Tried three times, since 11:30AM to post this.
This is the fourth.......

I just did some listening on a EU WebSDR and the Stew Perry contest is going strong over there. Believe it started at 15Z and runs 24hrs. That might wipe out any attempts at 160m BK QSOs this evening, but possibly we might have a chance late (4PM-5PM) Sunday afternoon if any one is interested. I will take a listen about then around 1810kc just in case. If anyone wants to brave the QRM & try it this evening let me know a time frame and freq.

GL & 73 de Bill W2ICE/4 - K4JYS

The serious ops will stay at 1810 and above... EU and most other DX
can't legally operate below 1810. You will find more casual operators
below 1810, but many of them will go QRT at 11PM or midnight EST. Your
best chance is to stay *below* 1810 and try late, ie. after 11 PM or
12AM tonight or near the end of the BK tomorrow. Tomorrow morning will
be busy also, guys will be above 1810 trying for JA with the more casual
guys below 1810 again.

GL BK... I'll be tapped out until the SP is over.

14712. BK part deux at K0SM

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-17 20:39:24 UTC
From: aflowers@frontiernet.net
Topic: 14712 Message: 14712
Attachments: 1 described; binary payloads are missing from this source WARC

I made a 80m tank coil (attached) this afternoon and I should be able to achieve "QRO" after midnight on that band. I'm seeing close to 50% power efficiency on 80m and a really nice tone without much if any chirp--very MOPA-like with the light wind we have for now. Hopefully it stays that way. I also found that I can just tap down the coil the "old fashioned way" and it works almost as well on 40m.
See you in a bit!
Andy K0SM/2

Tnx Eric for the info.
Then I will be down around 1805 +/- for tonight 12 mid nite est.
Tomorrow, will try 4:30PM (a bit early perhaps) and at 5PM (almost
dark here by then) around 1810kc. Will also make some calls between those times
depending on business on other bands.

Thanks Mike,

Possible problem tho. Those e-Bay clips are made for wire where the RELs are for straps. The new clips may not hold the strap well.

Could you send me one of your's for a try?

Lou

I bought a bunch from this guy back in May. 73 - Mike

Thank you, Roger. Let me see if I can come up with originals first.

Mike, The problem I see is not if they will open enough to accommodate the strap width, but rather, is the wire notch diameter large enough to make a good mechanical connection. Perhaps a bit of rat tail filing would do the trick.

Worked a few very weak stns awhile ago. As we do, I would lean in towards the RX to "copy better". CRASH went a static burst. Ended up on the floor....

Bill,

Yes, that would be midnight your time in the middle of the Stew Perry
soup!

Thanks, Bill. I will be calling and listening then.

14726. On 80M

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-18 05:45:49 UTC
From: Whitebear1122
Topic: 14706 Message: 14726

Went out with my wife and daughter to dinner then to see the musical White Christmas in downtown Saint Paul. What fun.

Got on the air around 11 PM and worked several stations on 80m. 80 is noisy and long. I worked N2BE, VE3AWA, K0SM, W0NYQ, W8AU. The closer stations were the hardest to work.

Temperature outside is -7F right now. Basement shack is nice and toasty. I can hear KB0MM calling AWA faintly with a strong echo on it, hence band is long. I'll call a few more AWA's before calling it a night if no one else is around. Hopefully 40 will be good tomorrow.

Going to try again this morning. Will start on 80M 3570 if itis clear or near as possible. Will use the new hartley. Even though it tested well on air before the BK so far it has failed to produce. I may try the monster hartley before 8 am on 40M on or around 7110 although it has nothing to prove being an old veteran. Should be warmed up and sending by 605am

Hear strong sigs from N8YE this morning on 3563. Sure sounds like R.A.C. but not sure – almost spark-like or slight oscillator FM. Shows interesting spectra just a bit wider than pure CW.

Hi Don,
Yes, good to hear you this morning and tnx for the QSO. Good copy down here in windy Pittsburgh this morning, the antenna swing sure adds an extra bit of '29 sound to my Hartley hi hi. Will be on 40m this morning on the TNT hoping to add some to the log.

14734. Charming Signals

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-18 17:02:34 UTC
From: Whitebear1122
Topic: 14706 Message: 14734

One of the many fun things about the BK 29 QSO Party is hearing the sounds from all those 1920's era transmitters. Each has it's own unique "charm". Just now I was musing over which one was my favorite and I came to the conclusion that there is no one favorite, as they are all charming in one way or another. I do love the beautiful sounds of the wind modulated transmitters. I recall one several years ago where the transmitter has a nice stable signal which then the wind was modulating at the OM said it was howling outside. So you could hear the transmit frequency gently rise and fall as the wire antenna gently swung in the wind.

The buzzers are so fun to hear. The worst (or best) was Bob W2ZM when he would run raw AC on the plates of his transmitter. He had a switch that switched between DC and raw AC. Sometimes you'd hear him with a nice tone, other time with the buzz, and then there was the time I heard him with both. He would switch between DC and AC during the report :) Now that was something.

The chirpy chow-pie chow-pit is a favorite as well. Reminiscent of the tales of the banana boat radio operators. When I built my first 29 transmitters back around 2001, I hadn't figured out loading and all the variables contributing to a stable signal. The chirp was so bad that the guy that dared coming back to my CQ, called me on the phone because he wanted me to hear it :) He answered the CQ out of sheer curiosity :)

One favorite was an ole friend Don N9OO whose transmitter didn't really have a signal or a tone, a spot on a frequency, or a buzz, or anything. It sounded more like a "vague presence" on the band :)

Often the stable transmitters have some charm. One of my earlier transmitters was very stable and had a bell tone to it due to keying or it's unique form of chirp.

The occasional transmitters that swish back and forth over several kHz are challenges to copy :)

So anyway, just musing over the charming sounds of the 1929 transmitters.

14740. Hammarlund TX Item WTB/WTT PN PL26860-G1, G2 160M installation kit:

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-18 23:21:07 UTC
From: N3IBX
Topic: 14740 Message: 14740

Hello All,
I know this is a longshot, but thought I'd give it a try just the same. I'm after the optional 160M installation kit for the Hammarlund model HX50 or HX50-A transmitters, Hammarlund part number PL26860-G1 or PL26860-G2. This kit would be used to add 160M to said transmitter.

If anyone has one of these kits for sale,trade or barter, I'd very much like to hear from you. My email address is: n3ibx@.... Thanks for reading this post and very best regards.

I have long been a fan of the 6l6tube and its variants. One that has intigued me is the KT88 which Iunderstand is the Euro designation for a 6550 more or less. my tube supplier has them currently at less then I pay for a good 6l6 so I ordered a 6550EH. I want to build a tx for the Linc Cundal event. The 10 watt power level limit is hard on us who live in an unpopulated area CW ham ops wise. With the Linc at least we have the option of running more power.
20 watts would give those who live in more ham density no particular advantage but the rest of us a fighting chance especially in off conditions which seem to be often the case for the BK. Andy is my closest station I think, then Lou. After that it is hundreds of miles. 250 to 400+

Anyway I am looking to build a fairly powerful one tuber. (at least 600 volts on the plate)Probably crystal controlled and want to also explore PA coil size effects. Mostly out of curiosity. Anyone used a 6550 or KT88in a TX already?
BTW also intend to put the 25l6 longfellow and 6aq5 pigmy thru their paces in the Linc event

Hello Don,
? ? ? ? ? ? ? ?Congrads on scoring a 6550EH! Out of curiousosity is it of the Chinese "Electro Harmonix" flavour? If so, then they are fine tubes. You'll be very happy with it. A pair of 6550's in what I believe to be AB1 linear service, made 100W output in the Central Electronics models 100V and 200V transmitters. With 600VDC or even less on the plates, I don't think you'll be disappointed with it. They make lots of power and are even FBOM in audio service as good modulator tubes. I've swapped out the original 1614 tubes in the modulator of my EF Johnson "Ranger" with a pair and they easily outperformed them.?

The best of luck with your 6550EH, and please let us know how it works out in your transmitter.?

BTW, I've purchased a pair of Chinese "Shuguang" KT66's for use in my "Heathkit-Williamson" W5M audio amp and they worked out quite well. IMHO the Chinese tubes of recent manufacture are just about as good as anything else, and they cost quite a bit less when buying them new over comparable American or European tubes.?

Mod-U-Later,
Joe Cro N3IBX

14745. 2016 BK Wrap-up de W2ICE/4

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-19 14:56:39 UTC
From: Bill Stewart
Topic: 14745 Message: 14745

GM All,
Another BK goes into the history book. First, a thanks to AWA for allowing me the honor of using Bruce's call for this years event. It was a lot of fun.

As is the usual case, the second weekend is not quite as active as the first. The first weekend I made 49 contacts...the second weekend only 13. Looking back over last years log (K4JYS) there were about a dozen stations that I didn't hear this year. Seems band condx were a little off too ....never heard more than a peep from western stations....MN was about as far west as I heard/worked. Heard a couple of the MN guys which I could not work. Strangely, late Sunday PM, I could not hear a thing from Ron, N4GJV (also in NC), as he was worked by several stations on 40m. But, on the other hand, sig. rpts for this station were pretty good and stations worked were also pretty good on 40 and 80m. Tnx to Steve, VE7SL, for the 80m report. Also had quite a thrill when DJ5RE called me, on 80m, the first w/e....my first big-pond jumping QSO with a 1920s rig. Only worked three stations on 160....the second night there was the SP contest, and a late effort, this past Sunday PM resulted in nil....had a storm come thru plus some QRM around 1810kc.
So the totals are:
40m - 23
80m - 36
160m - 3
TOTAL: 62

I think Scott, WA9WFA, gave a great narrative on the sounds of 1920s radio. I will just add that K4LJH had the most 'unique' note that I heard plus I did hear N8YE using his buzzer rig....what a great variety of notes...truly the sounds of the '20s. The oldest rigs worked here was a '22 Meissner at WU2D, a '24 Hartley at K0SM and the 160m rig here, a '24 Meissner.

Thanks to all who filled up the log. Already looking forward to next years event. Lou, how many days and counting?

73 de Bill W2ICE/4 - K4JYS

PS: I will be sending a copy of the log to Ed, K2MP, so anyone wishing a W2ICE/4 QSL can send requests to Ed.

Thanks Joe, Good info.
I have been very pleased with Electro Harmonix tubes and in fact my 6l6 of choice is the 6L6EH "tall boy"
my tube supplier Jon at Thetubestore in Hamilton ON has the 6550 on sale for less then 6l6s at the moment. The EH tube was up from the cheapest but they have become one of my preferred brands so I splurged despite my Schwaben heritage. Since I only ordered one he emailed wanting to know what I was up to. said everyone buys a matched pair so my order got his attention. By the way his service is wonderful. Often for me overnite. BTW got a pondhop invite tonite with the Collins. Here's hoping. "Hopping hoping" I guess ;>)

Thanks Mike -

Greetings AWA Group - I wanted to share that I've enjoyed the BK banter over the past few weeks - along with a note to thank those who I was able to log during my first BP QSO party. Working when time was available and when the bands permitted I was able to log 15 contacts on 80 meters. My TX is a 29 TNT (two 10 tubes) still on it's original bread board. Now that the event is past I can tear it down and mount it on a permanent board, already sanded and oiled.

Here's a shot of it all hay-wired up - Note that the key shown is only for tuning and development. I used a J38 next to my Collins 32S-3 receiver.

Image may contain: table and food

I look forward to future projects as well as banter from the group.

Background:
Short version, I got my ticket in 1985 - mostly work CW on my 32S-3 / 75S-3 - belong to several clubs, serving as president and directory for the SARA club here in Stillwater.

A more complete BIO can be found here http://qrz.com/db/N0GRM

73 to all - and thanks again,
Peter N0GRM

Peter,
Very nice!
I listened to the recording of the QSO with KB0MM on your QRZ link. It has a great sound....surely you didn't have the key attached to the breadboard for that, did you?

I need to give a big shout out for Bill K4JYS for operating as W2ICE/4 this year. Bill won the BK 29 last year and was given the opportunity to run the Bruce Kelley special event station this year. Thanks Bill for working the special event station and working so many stations! Your QSO total of 62 is outstanding and puts Bruce’s call in a lot of our log books.

I was pleased to be your first QSO in the event, and I heard you often on 40m and 80m all hours of the night.

Thanks again! 73, Scott WA9WFA

A challenging 29 event for me this year. I missed most of both Saturday nights this year for the first time ever due to scheduling conflicts. The first Saturday night I got on for about 1/2 hour at the start, and then again at 11 PM. The second weekend I only got on after 11 PM. So that kept me away from the prime time Saturday night 80 meters. I was hoping for more late night activity but it was pretty quiet. I'll admit too I couldn't drag my butt out of bed at 5 AM to work 80m when it's good :)

Propagation was terrible for me in general. The band seemed to be either shot or long. I only worked some 3 MN stations where as I usually work 10-12. Never heard my ole buddy Harold KB0ROB and I usually hear him all the time.

I was pleased to work W2ICE/4 both on 40m and 80m. What a treat! It looks like Bill worked 3 stations on 160m. Did anyone get a clean sweep of 40m, 80m, 160m with W2ICE/4? What about W2AN ? Did anyone work the AWA flagship station W2AN? I don't know if they were on the air.

My ole1928 Colpitts (pair of 210's in push-pull) was a charmer on 80m and a bit squirrelly on 40m. Not as jumpy on 40m as last year. I have a couple pictures of it up on my QRZ.COM <http://qrz.com/> page.

So in spite of my situation, I had a ball making the 20 QSO's that I made! 1929 is so fun!

Our thanks to Bill K4JYS in North Carolina for running the Bruce Kelley W2ICE/4 special event station this year. Great job Bill! Who ever wins the 29 this year will be extended an invitation :)

It was great working everyone I worked, and I am disappointed that I missed working those that I missed. It's like running into old friends on at the air each year.

73, Scott WA9WFA

It was a tough year for me too. Also scheduling difficulties but I did get in late the first Sat and all the second (due to freezing rain which nixed my fiddle work.) The first weekend I had real good success with the German dreipunkt set which is essentially a Hartley. In fact there is only one small thing I would change and will this morning so it is done for next year. It is a very cool running tube but makes decent power. All my 80M work the first Sat was with it. I had the old 40M TNT (the one I sometimes use on phone as well) on later Sat and logged a few but most seemed to have gone to bed. The second weekend my goal was to log a few with my new Hartley and I did. After that I was content and didn't push too hard. I really missed N1BUG as he could always find me. A very skilled operator, in my book. And also missed Larry and Lou which is unusual. They were usually almost a given. Haven't done my official log and other then making sure they know I was interested there is little point. Still it was fun. Several I could hear banging away. Some never stopped to listen more then about 3 seconds so probably spent the whole weekend calling with little success. Some of them I know from my AM adventures and it was nice to hear them on CW but I was unable to ring their bell from here. Getting ready for the Linc C

Very fun event. I tried jumping in last year using a 40M Hartley built at the last minute (Sunday morning maybe?) after making a non-AWA QSO with Bill, K4JYS, on 160M Saturday night. It didn't work very well, maybe squeaked out 1 or 2 QSOs on 40M with it. I was inspired afterwards to build some 29 gear and looked forward to participating in the 2016 event.

Over the course of the year, I have built numerous breadboard rigs, but for the BK I used a 29 MOPA on 40M that was originally my 2016 FD rig. I removed one buffer (24A) stage which was unnecessary for 40M operation and chopped the breadboard 8 inches shorter. The rig uses a 27 Hartley, 24A buffer, and 865 final. Photo attached. I spent a fair amount of time adjusting the voltage divider feeding the 27 oscillator. The result was a nearly chirpless, steady, DC note, with a slight drift. There were a number of comments on the purity, and even one station that only gave RST after I called him, apparently thinking I was not in the BK.

I used a different 29 MOPA on 80M the first weekend, running a 45 Hartley and 210 final, little more chirp and perhaps some AC modulation. During the week after the first weekend, I tore that rig apart and re-purposed the output tank coil to use on the 40M MOPA described above. That's what I ran on 80M the second weekend. Interestingly, the 80M note was never as good as the 40M note on that rig, so I'll have to spend some time working that out.

For 160M I used my 28 MOPA (photo attached) running a 210 hartley and 210 final. This is one of my favorite OT rigs. Very clean and steady note.

Lots of fun hearing all the unique signals. Might lash together a 203A Hartley for next year running on low B+. Also thinking about an early MOPA, maybe using 199s, 201s, or a 202 in the final.

23 Qs on 40M, 32 Qs on 80M, 4 Qs on 160M, total Qs 59. Missed much of the second weekend due to operating in the Stew Perry on topband.

Looking forward to the next one.

73 es MX/HNY
Eric NO3M / W8CDX

14757. 2016 BK Trivia

GM All,
Tnx Scott for the comments. Operating W2ICE/4 was surely a high point in
my many years on the air.

Here's a bit of useless information
(You can tell ain't much going on here this morning).
73 de Bill K4JYS

A break-down of rigs worked here:
(Incl. W2ICE/4)
Hartley - 20
TPTG - 5
Colpitts - 1
TNT - 6
MOPA - 6
Meissner - 2

Break-down by input power:
10w - 18 20w - 1
9w - 13 18w - 1
8w - 5
7w - 1
6w - 1
5w - 2
4w - 1
3w - 2
(Incl. W2ICE/4)

States/Prov:
NY-7; MN-5;
3 Stns ea: ME; PA
2 Stns ea: WI; MD; OH; NC; VA
1 Stn ea: IL; NJ; MA; KY; CT; VT; WV; NH; DE;
VE3-1
(Incl. W2ICE/4)
Total of 18 States + VE3 worked.

14758. K0SM BK report

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-20 14:59:31 UTC
From: aflowers@frontiernet.net
Topic: 14758 Message: 14758

My first BK is in the books. It's quite a wonderful combination of history, technical engineering, art, and even magic.

It might have been WB2QMY that first told me about the BK a few years ago, but I had never gotten up the energy to actually go and build something. Then about this time last year NW2K and I had just operated some winter contest at a multi-op, and the subject of old radios came up again. Somehow we decided that we would give this BK QSO Party a try, neither of us having any experience with "old" radios. I we both acquired a '27 and a handful of parts. I cobbled together the power supply from some old 50's medical equipment with a 5R4. Strangely, it oscillated on the first try...an amazing thing to me since the newest component was probably Eisenhower-era. I thought it sounded terrible when I connected it to the antenna and squeezed a mighty watt out of the tube on 40m, but VE3AWA managed to convince me over time that it was in fact the proper--if not wonderful--character of a transmitter. Lou was very helpful in suggesting parts and construction methods along the way, and had quite a lot to do with my narrowing in on a "1924" project. What a great time...Long story short, for me the BK was the culmination of about a year's worth of researching and building ham equipment from the ground up and learning a ton along the way. Both W2BSN and K2MP were helpful at the museum by pointing out some actual equipment that could serve as period examples of construction, and also allowing me to use the "big-bottle" tester at the AWA museum.

Anyway, I heard lots of that "character" this weekend, and very rarely did that character actually interfere with a QSO and it never prevented one of mine. I used the K3 almost extensively for receiving--signals weren't loud, and when they were they were pretty packed on 80m. I had a prototype 1924-style regen to go with the UV-202 transmitter for a true 1924 experience, but with a single interstage transformer designed for BC reception it has basically no selectivity. This was likely fine in 1924 when there might have been 5 signals between 80 and 75 meters, but this made it particularly difficult in the crowded CW environment of the BK spanning only 20 KC. (Yes, with my still-somewhat young ears I can pretty much hear the entire BK contest at once if I get the oscillator on 3570 KC or so.) This was a problem in the the 20's too, so I have some things to try from the literature. So there's one of my historical-engineering challenges for next year....

I ran the UV-203A on both 80 and 40m the second weekend, mostly because I found I can make a cleaner, more stable signal on 80 than I could with the with the other transmitter at the input power limit. The only problem I discovered is that it transmitted vibrations much better from the children playing upstairs in the early evening. It made for interesting random wobbulation in the signal when some little feet ran up or down the stairs. I found some bubble wrap and that helped a bit.

In all the second weekend netted me about the same number of QSOs as the first. In all, I think I ended up with 34Q on 80m and 14 on 40m for 48 QSOs total for both weekends. As someone who has quite a bit of experience with modern computerized radio contesting, I think I understand what a "dupe sheet" is for and why someone would use one. My best DX was probably KB0MM (on both bands, too!), which is fine for my cloud-warmers on a suburban lot. I'm pretty time constrained on Sunday, so I'm sure there was more to work on 40m that I just can't be around for.

I'm also pleased to work a clean sweep of the common circuits--at least one of each: HARTLEY, TNT, TPTG, COLPITTS, MOPA, and a MEISSNER...I even worked one "TGTP", which I

assume is operated left handed. I still want to know K4LHJ's keying circuit...
Most of all, this was a lots of fun! So much fun I'll have to try the Linc Cundall event coming up...
Thanks!
Andy K0SM/2

Topic: 14761 Message: 14761

Welcome to the AWA Group, Peter. Sorry we did not work...maybe next
year. Your 'haywire' TNT is a super rig. Its sorta amazing these things can work in such a state. I have a '24 Meissner I use on 160 in the same state as your TNT....has been like that for several years. I'm almost afraid to tare it down since it works so good. I imagine that our 'haywire' rigs follow the same trends as many of the orig. '20s ops...just look at a few of the old pictures. Be careful with your re-build.....it may never sound as good as it does now..Murphy is always lurking.....hi.

From: JAMES HANLON
Topic: 14763 Message: 14763

Sadly, I was not able to make a single contact on the BK. I had a lot of Holiday conflicts, but I did get on 40 for about a half hour Sunday morning and again for the last half hour of the contest Sunday Afternoon. There were signals on the band, but no BK stations were heard out here in New Mexico either time, and my calling "AWA" did not raise anyone. Guess I'll put the MOPA back on the shelf for a while.

73,

Jim, W8KGI

Just having fun with you old girl....my gosh, that is such a wonderful collection of work....just breathtaking in fact.

You almost need to have it on permanent display somewhere within the house but Nancy might draw the line in the sand? At the very least Lou, I would encourage you to get it all documented on a web site somewhere as it is so inspirational for those wanting to get started in '29 construction....and we can use all the new blood we can get!

From: Steve Flood
Topic: 14763 Message: 14769

I had the same luck as Jim here in Montana. I was stuck on 80m this year (no other working coil sets yet for the REL TX). I heard a single faint AWA last weekend but it faded away before I could make out a callsign. I got a late start this past Sat. night and heard zilch for AWA, and my calling produced zilch also. The only sigs heard both weekends were a few SKCC/WES, some digital near 3560, and Asian SSB early Sunday mornings.

It was a similar situation for me as well. Lou came to my rescue when I posted an inquiry about finding ceramic beehives. I suspect Lou has mentored dozens of us over the years as well as extending unconditional generosity to those in need!

Well my guess is that Nancy is off visiting the grandkids for a couple days and Lou became bold and dragged up all his fine equipment and set it out in the living like it’s always been there. He then had to hustle them back downstairs before the Misses got home otherwise it would have been the dog house for him.

Lou brought that long slatboard transmitter to the 2007 AWA Conference so I got to see it up close. He is a master craftsman for sure!

Your post brings up again a problem with the 10 watt rule. For folks who live in "the zone" like W1 W2 calls etc it is fine. But for those of us who live not so close in poor conditions we are at an extreme disadvantage. Allowing 20 watts for all the time would not change anything for those in reasonable reach of each other as they can already communicate much of the time but for those of us who live at a distance and have next to no one in reasonable distance who even owns a CW key let alone a pre 29 rig the extra power would put us on a bit better footing both in whom we could reach and whom we could hear. It would hurt no one and would expand the contests reach. Most of us I think are not in it for winning . Just for the fun. My 2 cents worth on the subject.

This was my experience as well. I got on 40 both weekends and called and called and heard no one. I like Don's idea about more power but I have a feeling for us on the west coast it won't matter that much. When most of the ops in the east are a few hundred miles apart it's obviously much easier. Out here there are only three or four of us and we're hundreds of miles apart.

Thank you for the comments...a bit embarrassing...but thank you.

Last Easter we had 19 family members here for dinner. After setting up two of three tables it occurred to me that this was my opportunity to see all the projects on display at once. I gave the men in the family the full tour. A few stayed, most drifted away.

Although I enjoy all aspects of building, I enjoy more seeing what others have accomplished. All the projects posted on the Group have elements of creativity, imagination, good workmanship, individuality and even the artistic.

Please post photos here of your work for all of us to enjoy...and steal ideas from.

Don, I agree, I'd like to see the power limit for the BK raised to 20 or 25W input. I think the 10W rule was set originally out of concern of not stirring up too much trouble or controversy with the 1929, and earlier sounding, signals. But I don't think a +3db change would make a big difference in that regard.

Hi Doug, I, too, wish you guys out west could make it back east more often, at least into the MN bee hive. There's usually a bunch of MN ops on during the BK. I think a higher power would cause problems. I believe one of the reasons for the 10/20 watt rule is to keep our sigs tamed down a bit. I think it is better we keep our 'unique' sounding signals at a low key. Plus, that power level is more '20s like....probably most hams back then used that power level. Can you imagine how many OO reports, cat calls, etc we would get even running 50 watts or so. Plus tubes for that power level are probably being gobbled up, at high prices, by the audio folks. Also, at the present power levels, we are all on about the same level....transmitter wise. A few suggestions: maybe a push to get more BK stations on out west. With a few more stations in the west, you guys might at least have a few more stations to work. How about working on the antenna systems...of course, this depends on how much room you have for wires, etc. Even a real good antenna for 40m would help. Years ago, from here in NC, I made it into W6 (80m) using my lowly TNT at abt 3w input. The antenna then, and still today, is a off center, single wire fed Hertz...a late 1920s antenna and now known as a Windom. I have also been fortunate to work Steve, VE7SL in several BK events...on 80 & 40m. I have used that type antenna for all BKs since around 2001, with good results. In future BK events, maybe more communications on this list would help everyone know when you guys think prop is best for west-to-east QSOs. As far as us easterners are concerned, possibly, we need to stay up later. I usually QRT about 1AM....I could hang a bit longer if I knew you guys were on. Here again, this list would be a good place to let everyone know what bands are working. Oh, when building a BK rig, go for the highest power the rules permit.....10/20 watts. Remember you can run 20w input between 5 & 13Z. There's no getting around it....west-east contacts will be highly dependent on band condx/prop. I have seen the times when, even with the high advantage of being in the east, condx were rotten and QSOs were few and hard to make. I hope you guys will stick it out and keep trying. Please pass along any suggestions you all have that might help get us all more e-w/w-e BK QSOs. GL....73 de Bill K4JYS ----- Original Message ----- From: "Doug Forbes dougforbes@...m [AWAGroup]" To: AWAGroup@yahoogroups.com Sent: Wednesday, December 21, 2016 10:21:16 AM Subject: Re: [AWA Group] BK Disappointment This was my experience as well. "You can run 20w input between 5 & 13Z." Which would be fine if folks would stay up but they don't. How about 15 watts then. or 20 watts after 2100hrs EST. I could have run a KW after midnite and it would have made absolutley no difference. Larry was already in bed I am sure as were many others. Old people don't do well late at night. When I get tired my call sometimes becomes VE3LYS. Doubtful it would be a problem. 50Watts? I wouldn't think that would be good but 20W or 15W?

I agree with this assessment 100%. The last couple of years I've pretty much "thrown in the towel" on the BK, although I do give it a try. This year was one of the worst. Only a couple super-weak stations heard. Conditions are always "poor" for this contest, it seems. lol. Increasing levels of man-made QRN on the bands make it even that much harder when trying to dig out weak QRP signals (and yes, I've tried all the QRN-lowering things....phased nulling, RX-only loops, etc)....With a typical self-excited oscillator, you might get 30% AT BEST of the input power...so a couple of watts out under BK rules. The 20 W input doesn't help a whole lot either. I don't know, but in years past it seems like BK QSOs were a lot easier to make on the E-W path. I don't think it's just "conditions" as everyone says every year. I think much of it is the increased noise floor on HF for many of us. I could be wrong with this generalization, of course, but it certainly applies in my situation here in suburban Denver. Personally, I think as long as the tubes and designs are from 1929 or earlier, ANY legal input power should be fair game. Times change, QRN increases EVERY YEAR (unless you live on a couple acres) and adaptation to these new realities may be required. Of course, more careful attention to to signal purity may be required with the higher power levels. My friend KD0VBR just built a push-pull Hartley with a couple of 203As (or 211s). 100 watts input, and 30 watts out. The tone is perfect. It can be done. Just my 2 cents 73, Mark AB0CW ----- Original Message ----- From: "Doug Forbes dougforbes@... Sadly, I was not able to make a single contact on the BK. I had a lot of Holiday conflicts, but I did get on 40 for about a half hour Sunday morning and again for the last half hour of the contest Sunday Afternoon. There were signals on the band, but no BK stations were heard out here in New Mexico either time, and my calling "AWA" did not raise anyone. Guess I'll put the MOPA back on the shelf for a while.

14785. 2016 BK

Hello Everyone, First of all, very nice display of transmitters Lou!! Excellent workmanship! I made 3 contacts, 2 on 40 and 1 on 80. I consider it a success because it was much fun! I have disconnected my Hartley and moved into the 30's with my xtals. Are there any Hartley meets during the year after the BK? 73 Jim kk4gfr

Hi Lou, Thanks for the LC skinny. I hope to be on. If I get my rock crusher power supply checked out, I might beon with my new 860 final. Hopefully that will put a little fire in the wire. If not, I'll be using the tried and true830B PA stage. The TX is described in the July issue of ER (#326).

Do to a scheduling mix up, I will not be the log collector this year. I am in contact with Tim re: any futurepossibility.

I do agree with many others who would support a power increase. As noise floors rise it has become harder for many guys in the suburbs to hear as they once did. On the other hand, if your noise floors are not over the top, 10W is more than enough to work from coast to coast under normal conditions on the low bands...even on 160...but...

another huge factor...for several years in a row we were blessed with good December conditions and coast-to-coast contacts were not difficult. The past three years have seen rotten rotten conditions, as the solar cycle has wound down (always the most 'radio-disruptive' part of the cycle). This should change, if things get back to normal or unless the sun's new 'normal' is something like what we have been seeing of late.

In reality, late Decemebr is a terrible choice for this activity as the low bands are often stuck in what is known as the 'mid-winter anomaly', a well documented condition that often makes bands like 80 and 40m total useless for normal transcontinental work. A far better time would be in November or in February, where band conditions are often much more favorable and there are fewer conflicts with other contests. Maybe we would have more luck persuading the higher-ups to change the venue dates rather than the power limit?

Don, I agree, I'd like to see the power limit for the BK raised to 20 or 25W input. I think the 10W rule was set originally out of concern of not stirring up too much trouble or controversy with the 1929, and earlier sounding, signals. But I don't think a +3db change would make a big difference in that regard.

But would have 8Woutput made impossible condx less impossible? In the past the East/West worked at the 10 input.

But I don't think a +3db change would make a big difference in that regard. If I read this correctly, yes it would, unless everyone runs a Hull Hartley. While this would make an Islander happy, it is not likely to happen. From experience, a rig with a good quality signal at 4 Out goes to hell at 8 with the tight loading.

For what it's worth, I agree with Bill's assessment.

Perhaps owing to my above average antennas, whenever I work the BK I get on air and email comments about my rotten signal. Some of them are quite belligerent, telling me to cease and desist "or else". I don't feel a 3 dB power increase (from 10 to 20 watts) will help much with east-west contacts. A larger increase probably would (say 100 watts), but at what cost? I suspect if more people get louder signals there will be more complaints and possibly bad publicity. As it is, for the most part BK stations have a fairly low profile.

The other factor is cost to build rigs. As you go up in power, the cost of appropriate tubes skyrockets. If one wants to build a mostly period correct rig, so do many of the other parts. This tilts the playing field in favor of those with deep pockets. I know, I know, it isn't a contest. But, if you really want it not to be seen as a contest, then perhaps consider not giving a very attractive plaque to the winner. That tends to make some people crazy (including me). Call it an activity night with no award or public score listing for prestige. Publishing a list of calls participating without listing number of contact or score would be good. Actually for me that would make working the BK much more appealing than the current format which by its very nature promotes aggressive competition.

I'm not a regular participant, obviously, so whatever the majority wants. I am just not sure raising power enough to really help is a good thing. I think Bill's suggestions about promoting more activity and improving antennas (where at all possible) are good. Antennas are everything. The ones out west with above average antennas are the ones who make it into my BK log.

Paul N1BUG

On 12/21/2016 12:00 PM, Bill Stewart cwopr@... [AWAGroup] wrote:

Hi Doug,
I, too, wish you guys out west could make it back east more often, at least
into the MN bee hive. There's usually a bunch of MN ops on during the BK.
I think a higher power would cause problems. I believe one of the reasons
for the 10/20 watt rule is to keep our sigs tamed down a bit. I think it is better
we keep our 'unique' sounding signals at a low key. Plus, that power level is
more '20s like....probably most hams back then used that power level. Can you
imagine how many OO reports, cat calls, etc we would get even running
50 watts or so. Plus tubes for that power level are probably being gobbled up,
at high prices, by the audio folks. Also, at the present power levels, we are
all on about the same level....transmitter wise.

A few suggestions: maybe a push to get more BK stations on out west.
With a few more stations in the west, you guys might at least have a few
more stations to work. How about working on the antenna systems...of
course, this depends on how much room you have for wires, etc. Even a
real good antenna for 40m would help. Years ago, from here in NC, I made

it into W6 (80m) using my lowly TNT at abt 3w input. The antenna then, and still today, is a off center, single wire fed Hertz...a late 1920s antenna and now known as a Windom. I have also been fortunate to work Steve, VE7SL in several BK events...on 80 & 40m. I have used that type antenna for all BKs since around 2001, with good results. In future BK events, maybe more communications on this list would help everyone know when you guys think prop is best for west-to-east QSOs. As far as us easterners are concerned, possibly, we need to stay up later. I usually QRT about 1AM....I could hang a bit longer if I knew you guys were on. Here again, this list would be a good place to let everyone know what bands are working. Oh, when building a BK rig, go for the highest power the rules permit.....10/20 watts. Remember you can run 20w input between 5 & 13Z.

There's no getting around it....west-east contacts will be highly dependent on band condx/prop. I have seen the times when, even with the high advantage of being in the east, condx were rotten and QSOs were few and hard to make. I hope you guys will stick it out and keep trying. Please pass along any suggestions you all have that might help get us all more e-w/w-e BK QSOs.

A few comments on Paul's post....de Bill K4JYS:

"whenever I work the BK I get on air and email comments about my rotten signal."
Paul, I have gotten those comments also, altho this year all the OOs and emails will not come to me...hi

---

"I suspect if more people get louder signals there will be more complaints and possibly bad publicity. As it is, for the most part BK stations have a fairly low profile."
Paul's statement is spot-on. Most of us BK'ers are operating well outside of today's 'signal purity standards'. I feel we have been lucky, so far, that the FCC hasn't heard our sigs (hopefully they have more important things to listen to) and sent some of us that BIG OO notice....I usually get a few from the ARRL guys tho. Also many of today's hams only know the 'rice box' sound and can't even give us a correct RST....thus more chances of complaints.

"The other factor is cost to build rigs. As you go up in power, the cost of appropriate tubes skyrockets. If one wants to build a mostly period correct rig, so do many of the other parts."
As it stands now, with our power limits, we can build pretty close to 'period' correct by using fairly inexpensive and available receiver parts. I am not a purest, but building as close to the 1920s time frame is a big part of the fun.

"I know, I know, it isn't a contest........"
"......the current format which by its very nature promotes aggressive competition."
Don't agree with the 'aggressive competition', however I do agree that it is not a normal type of contest....I like to call it an event. If it was a true contest we would be doing the '599-73' (and I'd be doing something else) contacts instead of stopping every-once in a while passing a few comments along. In all the years I have worked the BK, I have NEVER heard, been a victim of or perpetrated aggressive behavior of any kind. I think a better word would be 'exuberant' operating. In fact, I'm exuberant about the whole BK event....not just the operating. For me, it is just plain a lot of fun..... whether I make 20 contacts or more. It's gotta be based on fun, not winning, to stay up late, call and call, etc, try to pull out a wobbling, chirpy signal from the noise and when you do log the station.....well, you have accomplished something many hams know nothing about....what radio was like in the 1920s. Go back and read Scott's (WA9WFA) recent email RE. "Charming Signals".....to me this is one of my main enjoyments of the BK and I hope that never changes.

"I'm not a regular participant,........"
Paul, wish you would consider joining in more often.

Well itis kinda disapointing to here these expressions. Fine to say that when 20 or 30 of you live a hundred to 150 miles from each other. Larry for instance is if memory serves 4I3 form me. Lou about 180. Andy is the closest around 70 to 80miles. not the same from here. And yes I do have an excellant antenna farm. Anyway whatever. I am also in it for the fun so hopefully we will get some decent conditions again like a few years back. In the LC I am dragging out the longfellows.

I think I might have found my answer--"vulcanized fiber", "vulcanized fibre", and "fishpaper" all seem to be the same approximate stuff. I found some adds from the "Deleware Hard Fibre Co." and "American Hard Fibre Co." in some radio/electronics rags from the early 20's, and this is what they were selling. Like phenolic thermoset resins (Bakelite, Condensite, Garolite etc) it too was and still is used for its mechanical strength where electrical insulation properties are needed. Like the phenolics, it also is resistant to most solvents.
It's not to be confused "fiberboard"--a wood product like MDF or particleboard.

I'm looking at an article for winding a spiderweb
coil. The suggested material is "1/16in fiber",
which must be some kind of 1/16" thick sheet that
is stiffer than cardboard and can be cut/sawn to make a
spiderweb form. What is this stuff and is there a source
of material (or dead ringer) in this century?
There
is such a thing as "fiberboard" available today
but I'm not sure if its the same stuff. The article
really heavy cardboard *might* work but fiber would be
better...
Thanks!

Congratulations Jim on your two 40 meter and one 80 meter QSO’s with your 1929 rig! That is an accomplishment for sure! My first 1929 QSO Party wasn’t because I was still struggling with the 80m MOPA and didn’t get it done, so my score was a big fat ZERO. You got three more than me dude :) My 2nd year score was something like 14 stations on 80m and I thought I had died and gone to heaven with that score. hi hi I suspect you’ll be racking up more QSO’s next year. 73, Scott WA9WFA

14808. Re: [AWA Group] BK Power Discussion - LONG

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-22 03:18:33 UTC
From: Whitebear1122
Topic: 14763 Message: 14808

Hi All, The BK 1929 QSO Party power rules have been simmering under the surface for a while now and may now be time for a change.

I am happy to talk about it. There is nothing “sacred” about the power other than it’s part of the original rules that Bruce Kelley, Batterson, Cundall et. al came up with at the start of the 29 QSO Party around 1991. Not being there at the time, I can only speculate that the power limit all came down to just one thing: Authenticity. I think Bruce just wanted to run the real 1929 transmitters that were popular back then, not the ones owned by the very few rich people, but the ones owned and operated by the majority. I have several hundred 1929 and earlier QSL cards and most of them are running 9 watts input or 4 1/2 watts.

I will also note that the first 1929 QSO Party had around 19 stations participating, all in the New England area, states bordering on New York (Bloomfield). So the contacts were much easier to come by with station being 50 to a couple hundred miles apart. That was then.

Fast forward to today where there are thousands of miles separating us. There is still a large contingent of 1929 stations in the historic New England area, Maine through New York, along with some down south like Bill JYS, and Ron GJV, and then a big bunch of 10-12 stations out here in Minnesota, Wisconsin, Illinois, then the few guys out west like KK7UV, Mark AB0CW, Howie WB2AWQ, Jim W8KGI, and our buddy Doug WA6VYN in California It’s damn tough working the New England and SW/W stations and I feel guilty giving out 339 RST and thinking the signal is not even that good. Thank goodness for the Elecraft KX-3 receiver with the razor sharp filters. Still that doesn’t make up for poor propagation. Just a few years back propagation was great on 80 meters at night. For years I could count on 80 meters to start rolling in around 5:30 PM and I’d work all the MN stations, then around 6:30-7:00 the band would go long and I’d hear all the east coast west coast and southern guys. Not now though.

Some have speculated that the lower QRP power levels keep this event under the radar of the FCC and OO’s. I don’t believe that was the reason for the power level in the first place but it does help keep us under the radar.

For several years there was a local OO living about 5 miles from me. The guy was a big cw net operator and on every Saturday night running nets. You can imagine that I was on his OO radar every 29 QSO Party weekend :) I think he gave up sending me OO notices. Thankfully he finally moved away. Frankly I ignore the OO’s. Let them go up and solve the horrible behavior on 75 meter SSB in the evenings or 7200 kHz SSB first, and only then come down and hassle me over my chirpy pip squeak transmitter that is not bothering anyone … hi hi

Personally I do not have a problem with raising power limits in the BK 1929. I’ve been thinking about it for the past several years, thinking that it’s time. Last Spring I consulted with one of the MAJOR 1929 guys who has won probably more 29 QSO Party’s than anyone, and I respect his opinion. He said he would be fine with a power change. He said it’s not about the power. He said it’s about the building of a 1929 style rig using 1929 period tubes, putting it on the air, and contacting other 1929 stations. This guy operates

1929 equipment all year long. I agree with his thoughts about the 1929 power.

I'd love to put a Colpitts on the air with a pair of 211's in push pull, and get 30 watts output. I'd love to give W8KGI and AB0CW a 569 report instead of a 229 or not hear them at all.

DISCLOSURE STATEMENT: I am in an awkward position right now. I have resigned my commission as your AWA 1929 QSO Party manger effective as soon as I complete the tabulating and writing the 2016 29 QSO Party AWA Journal results article . I announced this last Fall and notified Tim Walker W1GIG AWA Amateur Radio Manager as well as notifying the Amateur big wigs at the Antique Wireless Association. After 12 or 13 years it's time to pass the event management on to another. There is no illness or sickness driving this, no issues or conflicts. It's just time to pass it on.

With the approval given by Tim Walker W1GIG, your new 1929 QSO Party manager is Dave Parker WB9WHG in Madison Wisconsin. As the former manager I can only recommend power changes to the new management and help consult with the rules changes if asked.

It has been a pleasure serving as 1929 QSO Party Manger for all these years and I hope Bruce Kelley and John Rollins are pleased with how I managed their QSO Party. Harold KB0ROB told me a couple years ago that his close friend John Rollins told him on the phone that he was very pleased with how I've run the event. That meant a lot to me because I've tried hard to do right by Bruce and John. I think my first 29 QSO Party as manager was 2004.

You 29 guys are unique in amateur radio. You guys go way beyond the appliance operators by actually building and operating your own 1929 gear. Screw the 599/qth/name/WX//73 guys, it's all about what oscillator configuration did you build, tube? plate current? plate voltage? efficiency? power output? chirp or charm?, coil diameter and turns? etc… This is fun amateur radio!

73, Scott WA9WFA

Rules are important and many contests/events have provisions for checklogs. Perhaps BK could accept a checklog from a station that violated the power rule. That checklog could also include QSOs with non-BK stations (I made many more Q's with non-BKers than BKers). More power, more QSOs, more fun...but no plaque. However, there are some that frown upon those that violate the rules willingly and submit checklogs. This is a hobby and we're all trying to learn while having fun.

If someone would complain about a BK signal, they will complain regardless of the S-meter reading. Thankfully, that ham is in the minority. Radio history is important and I'm reasonably certain that our governors will cut us some slack for a few hours every year.

As I was talking earlier I ordered a 6550 tube (KT88 eq) These tubes are giant 6l6s using the 7ac pinout but capable of big power. Partly due to their size perhaps but mostly due to their ability to stand a heavy load at 600+ volts. I held a metal style early tube in my hand beside the 6550 just to give an idea of the difference in size. And just for fun I pulled the 6l6 out of my breadboard 80m rig and plugged in the 6550 just to see is there any difference even at the normal 6l6 voltages. If the scale on my FS meter means anything yes. A substantial difference. Perhaps 20% or more with the 6550 tube. Now I have to build a 600v underload supply for the breadboard rig. I have several 600 volt supplies but they are all 12 volt filaments because they are feeding WW2 military sets with 807s or 1625s. Anyway this is something I wanted to explore for several years and my supplier had these tubes on for less then 6l6s at the moment so I seized the oppourtunity. It does not seem to have any trouble running as a 80M osc. Keys well and starts well. Maybe I should build another Longfellow for 160m with it. 6l6 driving a 6550. Anyway more fun in the hobby. donVe3LYX

Alex, As far as I know, the words "cathedral" and "portable" don't go together. My Cavalier portable has broadcast band plus two short wave bands with tubes 1R5, 1U4, 1U4, 1U5, 3V4. It has typical square wood cabinet with two-tone green leatherette covering. I would describe its cabinet style as "suitcase". If interested, I can send photos as soon as my camera batteries finish recharging. Mike, W6MAB

☐

Has anyone any information an a Cavalier cathedral portable? This one has removable doors on the cabinet front and rear, and a carrying handle on the top.

The only identification is the "Cavalier" name on the indicator bezel.

Don,

I think this is a great idea. There used to be a very active glowbug roundtable, that was on just about every weekend....informal...just a bunch of hams that would put on their old homebrew gear or even just their tube rig on CW....this was back around year 2000 or thereabouts. Really a lot of fun. That has long since faded into oblivion as far as I know (although ER lists it as an active group).

So yes, why wait just for once a year for the BK to fire up the 1929 stuff (I know there are some that do use them year round) ? Start building higher power tx rigs, based on 29 tubes and designs....or just use the regular 1929 rigs we already have...and strive for a good "note". Once a month would be great. And of course it would be great "practice" for the BK.

I mentioned my friend KD0VBR. His twin 203A/211 Hartley is now driving a twin 860 power amp ! 100 watts OUTPUT. A fine 1929 rig in my opinion, lol...albeit the tubes can get pretty expensive. He is running 1200 VDC only on the 860s (which are paralleled) and is even using a PS with 866s in it. I can tell you that it sounds like a modern tx on the air.

I have a 40 meter 10 osc to 860 rig that has been sitting on the shelf for years, waiting for me to finish it. I just might have to finish it now.

14816. Marconi in Dorset

Yahoo group: AWAGroup (2014 — 2016)

Group,

Here is something Ian, G3ZDQ sent to me recently. Perhaps some here are also interested in the history of our hobby as well.

73, Lou
VE3AWA

I have attached a couple of PDFs and a photo which I thought you might find interesting. The photo is of the Haven hotel in Sandbanks Dorset circa 1900. This is where Marconi carried out some of his early wireless tests to the Isle of Wight at that time. The text below is copied from an article written about his work in Dorset.

The two PDFs are copies of a couple of hotel bills for G Marconi from the Haven hotel around that time. My friend Jim Taylor, now a silent key, had the originals but kindly made copies for me. You said you were interested in radio history so I thought you might enjoy them. Marconi obviously liked a tot or two!

Sandbanks is now a very popular tourist area. The Haven hotel is still there and the room Marconi used is now a lounge but preserved within the newer hotel building. I used to work in Poole at the Plessey Company quite close to Sandbanks, so know the area quite well. I don't think Marconi would recognize it now though!

Ian G3ZDQ

Something in the air
Brian Faulkner looks at Marconi’s pioneering work on radio on the Dorset coast
Published in February ’11

Guglielmo Marconi, credited with being the ‘Father of Wireless’, was born in Bologna, Italy. He wasn’t a particularly clever scholar but was captivated by what he called, ‘the idea of transmitting messages through space by means of etheric waves’. With the Italian government showing little interest in his experiments the 22-year-old arrived in London in 1896 and, after staging successful experiments in front of scientists and the military in London and on Salisbury Plain, he was convinced that, in the short term, wireless would offer greater benefit at sea than on land. The following year he arrived on the Isle of Wight, with his assistant George Kemp, where he set up the world’s first fixed transmitting station at the Royal Needles Hotel.

We have a very accurate account of Marconi’s work at the time from the meticulous diaries that Kemp kept. On 24 November 1897 he wrote: ‘purchased lower mast, topmast and sprit at Southampton. Hired a tug and towed it to Alum Bay, landing it at the bottom of Alum Chine. It was far from easy work in bad weather to transport these spars to the top of the cliffs

and across the lawn in front of the Needles Hotel.'

On 7 December the experiments began. 'We started experiments using either the Solent or Mayflower, tugs belonging to the South Western Railway Company at Lymington, the object being to steam over a triangular course each day and noting the signal strength. To Bournemouth Pier, then on to Swanage Pier with a straight run back to Alum Pier.'

Despite contending with south-westerly gales, rain and dense fog, good progress was made and signals were received at distances of up to eighteen miles (29km) allowing Kemp to write, on 23 December, 'We were satisfied that we could erect a station at Bournemouth and another station at Swanage and keep them in communication by wireless telegraphy day and night throughout the year without interference.'

Marconi now turned his attention to finding a suitable site to, as he wrote later, 'prove that wireless telegraphy was not a myth but a working reality.' In January 1898 he arrived in Bournemouth and set up a station at Madeira House, in the vicinity of the current Bournemouth International Conference Centre. A local journalist wrote, 'His object in Bournemouth is to signal a considerable distance, namely to Swanage on the west and the Isle of Wight on the east or to ships at sea. A flagstaff has been erected and from the top of this a wire runs down to apparatus in the house where instruments for receiving and transmitting messages are placed. The instruments to the ordinary observer are very simple in appearance and can easily be accomodated on a table three feet square.'

After some early teething problems, Marconi gave a series of successful demonstrations from the Needles Hotel to Madeira House on 9 January 1898, in front of his company's directors and local residents, Lord and Lady Tennyson, who took away with them a piece of tape that recorded one of the messages.

Towards the end of March, in a raging blizzard, Kemp managed to erect an aerial at the old Lloyds signal station at Swanage, over 200 feet above sea level. Wireless pioneers were a hardy crowd. His diary records that, 'I then laid down in the snow and joined up to the receiver at the same time covering my head and the receiver with the large cape attached to my waterproof coat.' He immediately heard signals between Marconi, in Bournemouth, and the Needles Hotel.

During these trials the liner Carisbrooke Castle was sighted passing the Needles outbound on her maiden voyage. Her position was passed by wireless from the Needles to Bournemouth and by inland telegraph to London. The telegram read, 'Steamship Carisbrooke Castle, Donald Curie Line, outward bound, passed the Needles at five minutes past six.'

Among the many prominent people who visited Marconi at his stations was eminent physicist, Lord Kelvin. He became the first person to send a paid message by wireless when, on 3 June 1898, he sent a message to mathematician and physicist, Sir George Stokes, insisting on paying 1s (5p) royalty on it.

The message read:

'To MacLean, Physical Laboratory, University, Glasgow.

Tell Blyth this is transmitted commercially through ether from Alum Bay to Bournemouth and by postal telegraph thence to Glasgow – Kelvin'

Earlier Kelvin had been extremely uncomplimentary about Marconi's efforts. 'Wireless was all very well,' he said, 'but I would rather send a message by a boy and a pony,' so this

was his way of apologising and something in the way of a gesture of confidence. The message was handed in at Bournemouth at 2.30pm and received in Glasgow just 50 minutes later.

After all the effort he put into finding a suitable site for his station, Marconi soon fell out with the hotel management over the cost of the 115ft (35.5m) wooden mast that was in their grounds. Kemp recorded, ‘Sept 24th to 28th, trouble with hotel manager Mr. Miller.’ On 30 September he wrote, ‘Transported masts on a timber wagon and apparatus in a van to the Haven Hotel, Sandbanks.’

In the latter years of the 19th century Sandbanks consisted of just two hotels, a coastguard station and a few private houses, one of which belonged to Lord Wimborne. Marconi carried out a great deal of experimental work here and a local boatman spoke of a large, east-facing room on the ground floor that served as the main laboratory although he also used huts in the grounds. He often spotted Marconi through the window standing in front of a ‘great flat instrument, several feet square. He looked as though he was playing a piano. Sparks kept flying from this strange machine.’

Marconi lived and worked on and off at the hotel, with members of his family, until 1926. Visitors noted that meals were taken at a communal table, with Marconi and his mother and brother being joined by Dr James Erskine Murray – who had studied under Lord Kelvin and subsequently worked with Marconi on many of his experiments – and his wife, the rest of the staff, and indeed anyone else who happened to be there at the time. Following dinner there was often a musical interlude. Murray would play his cello, Marconi’s brother, Alfonso, his violin, with Marconi, himself, accompanying them on the piano. Today the hotel’s lounge is named in his honour.
On 28 February 1900, the 14000-ton German liner, Kaiser Wilhelm der Grosse, probably the most famous liner of her day, sailed from Bremerhaven with Kemp on board, the first liner to be fitted with wireless. Once in the English Channel, the ship’s wireless operator made contact with Marconi’s stations at the Needles and Haven Hotel and, before the ship was out of range of the Isle of Wight, many of her passengers had taken the opportunity to try out this new-fangled invention.

In later years, Marconi became a Captain in the Italian Naval Reserve, and said on more than one occasion that he felt more at home on the sea than on dry land. ‘Nothing can replace the charm and freedom of the sea,’ he said. His yacht, Elettra, was a floating laboratory, and was often seen in Poole Harbour lying just off Brownsea Castle. Marconi carried out a great deal of his experiments in long-range communications on board. Elettra, receiving signals transmitted from the Marconi company wireless station at Dorchester. This station was built in 1927 and was known as the ‘Beam Station’ due to the way the radio signal was transmitted. It opened on 16 December with a service to New York and was followed shortly afterwards by a route to South America. By the end of 1928 services to Japan and Egypt had also been inaugurated. In 1929 equipment was installed to enable the station to conduct tests with Marconi on his yacht which, at the time, was off Genoa. The tests were apparently, ‘quite satisfactory.’ The Post Office took the station over in 1949 operating Associated Press services and world-wide maritime services. The beam aerials were prominent on the Dorchester skyline until 1966 when the last one was demolished and the station itself closed in April 1978.

When Marconi died in July 1937, the Bournemouth Times and Directory reported, ‘Bournemouth may take special pride in the fact that it was here that senator Marconi conducted his first experiments at the close of the last century, and there are those still living in the town who remember him working in their midst. There is not a wireless listener in

Bournemouth or anywhere else who has not lost a good friend in Senator the Marchese Marconi whose death in Rome this week has been universally mourned.’

14817. Re: [AWA Group] BK Power Discussion - LONG

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-22 19:51:32 UTC
From: aflowers@frontiernet.net
Topic: 14763 Message: 14817

My two cents.
It seems to me that if more power were allowed, it should come with the reminder to be responsible and know your station its limits, and probably take some steps to mitigate any potential problems. In the end we are responsible for the operation of our transmitters, whatever we choose to do. In the spirit of 1929 and the vision of the BK (and being so new to all this might be a little presumptuous having not known Bruce), I'm trying to look at this from the 1920's perspective: What would Ross Hull do?
What I've found in my short travels so far that all the "scary" spectral purity issues: chirps (and other FM effects), clicks, harmonics, parasitic oscillations, and other modulation effects are all addressed in the period of the 20's, and have authentic (I hate that word) 1920's mitigations. I really don't see any reason that period 1929 construction techniques can't actually meet the letter of the law, not just the spirit (which is don't cause QRM to anyone--*especially in other services*--by bad design or adjustment, and from what I can tell we're generally pretty good about this, today whatever else). This is an operator- as much as a construction thing, and you can address all this to your satisfaction without resorting to knowledge or techniques to modern for any tastes.
Keeping the power down does minimize some risk, I suppose, but good 1920's RF design can be pretty good and something to be proud of, I think.
I personally am looking forward to building a "50W" MOPA and learning to neutralize it, regardless of whether I run it at full power or not.
So getting back to Mr. Hull...Ross Hull spent lots of time in the ARRL lab working on this stuff to show us just how good things can be with primitive self-excited oscillators. I think he was successful in diagnosing the biggest problem at the time (and probably the most obvious today with our self-excited oscillators)--the FM affects of changing plate voltage on the frequency of the oscillator. This is what Ross Hull's seminal "Overhauling the Transmitter for 1929" (Aug. 1928 QST, p.9) is *really* about. His point was that you can adjust a transmitter so that changes in plate voltage don't cause the transmitter to change frequency much if at all. If you accomplished this, the regulation of the power supply becomes much less important--even an AC supply would be acceptable. By adjusting the plate voltage and measuring the change in carrier frequency he found what parameers affected this and how to get there. In the end it still chirped a little and I'm sure it still had some of that magic sound--just not pathological amounts of it. After all that, he then he describes the pretty transmitter on the first page to serve as a model
...but all the while under the umbrella of belief that crystals and MOPAs are still a better bet from a compliance perspective!
For those who have not seen it you can find a copy of this article (the original copyright has expired) at W1UJR's
website:http://www.w1ujr.net/Overhauling%20the%20Transmitter%20for%201929.pdf
Now, when the supply dropped from 400V to 300V (or less!) on key down, the transmitter only would move a few 10s of Hz instead of 3KC. A 3KC chirp might just sound like a loud click to everyone in its path, but its not a "click" (or "thump" in 1929) in the sense of having too fast of a rise and fall time (AM component). It's just a really fast frequency sweep.
I suspect adding an RCL click filter around the key (or keying the transformer primary) would just slow down the sweep rate and probably make things worse! 10KC chirps were not unusual with bigger tubes, apparently.

Thus, in Mr. Hull's eyes, unfiltered AC supplies that went from zero to full plate voltage every 1/60s or 1/120s were acceptable so long as one could minimize the FM effect through proper adjustment. Extreme case in point: Ross Hull made a 1929 self-rectified set using two *UX-852s* and got the thing corralled into about 500Hz including sidebands (QST Feb 1929, p. 23). This is a transmitter in which each tube sees zero-to-at least a kV swings every 1/60 second, and its basically two free running oscillators that have to be tuned to the same frequency sharing the same tank circuit but not the same blocking caps or internal tube capacities! It would make a quite a noise today, but pretty amazing given what it is. I don't think that every tube and transmitter can be quite as good as Mr. Hull's results, but it definitely worth tinkering with to get to know your transmitter. This too is in the spirit of 1929, and in the end I'm sure there will be some lovely "character" to spare when all said and done!
Probably the most important thing BKers can do is have the situational awareness to avoid interference to others--a characteristic of any good operator--while carrying on the mission of promoting radio history. I thought people did a very good job of that from what I could hear.
Fun stuff...
Andy K0SM/2

On Thursday, December 22, 2016 8:18 AM, "dfaklis@frontiernet.net [AWAGroup]" <AWAGroup@yahoogroups.com> wrote:

Rules are important and many contests/events have provisions for checklogs. Perhaps BK could accept a checklog from a station that violated the power rule. That checklog could also include QSOs with non-BK stations (I made many more Q's with non-BKers than BKers). More power, more QSOs, more fun...but no plaque. However, there are some that frown upon those that violate the rules willingly and submit checklogs. This is a hobby and we're all trying to learn while having fun.
If someone would complain about a BK signal, they will complain regardless of the S-meter reading. Thankfully, that ham is in the minority. Radio history is important and I'm reasonably certain that our governors will cut us some slack for a few hours every year.

I just had a thought...dangerous, but here 'tis.
I got the W1AW post re. SAQ coming on with its commemorative
Christmas eve transmission. Plus Commemorative Fessenden Christmas
Eve 600-Meter Transmissions, which got me to thinking and some
of you radio history buffs help with this....is there any special event
in pre-1930 (1929 and back) dealing with amateur radio or radio
communications in general, that might be significant enough for us
'29ers to get on the air, with our rigs...any power ya think you can get
away with...sorta like SKN? There must be some significant date that
we could commemorate by getting on the air for a few hours...or more.
Probably numerous Marconi dates, Armstrong dates...and others just as
important. A KISS type of event...no score...no winners...no awards...
minimal log submissions, maybe a list of participants, etc...only requirement
would be a '20s xmtr (any type used in the '20s, even xtal)....and CW of
course....and rcvr too if ya have one.

Again, just a thought...comments?...tnx...73 de Bill K4JYS

14826. Tr: BK Power Discussion

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-23 01:42:13 UTC
From: JAMES HANLON
Topic: 14826 Message: 14826

Apparently my "disappointment" post several days ago stirred up some good discussion, and that's great. Here are a few thoughts I've had reading over the many good comments.

Use a good antenna for better results - my antenna for 80 and 40 is a 268 foot center-fed Zepp up about 35 feet. While greater height would no doubt help, that just is not in the cards, and this particular antenna does really quite well on another 80/40 operating event, the Classic Exchange.

I really enjoy working the BK, even though I have not chance to "win." Making a few QSOs with my 10Y/10Y MOPA or my 210 Hartley is a blast. There are probably three things that were responsible for my lack of a QSO this time.

1. I only spent about an hour on the air - entirely my fault of course. But this time of year, at least for me, is very busy with preparations for Christmas and family obligations that I personally have decided must take precedence. Perhaps (another) running of the BK at some less busy time of the year would allow me to spend more time on the air.

2. As many have mentioned, getting a signal from New Mexico out to Minnesota or New England or the East Coast with only 10 watts input can be pretty marginal at times. It's a two-way problem, you can't hear my weak signals and I can't hear yours. My MOPA will run more power and still put out a note as good as it has at 10 watts, so I could add somewhere between and 3 and 6 dB which would help you hear me. If you could also increase your power, that would help me hear you as well. Think about this. What would happen if we just dropped the power limitation from the BK rules completely. Guys who could might run a bit more power which would increase the number of cross-country QSOs and make for more fun for those of us out in the hinterlands, It wouldn't prevent the guys who are close to one another from continuing their contacts using lower power. Most folks would continue to put a rig together using a 27 or a 45 or a 10. A few enthusiasts might build a really big rig with a 203A or a 211 or some such tube, but so what. No one running low power would have any less fun. It would just add a little more to the total activity in the BK, and that would certainly not hurt anyone.

Actually I have similar thoughts about the power restrictions in the LC "contest." It encourages folks "back east" to put on low power signals which make it more difficult for those of us out west to make any contacts. My response to that is been to forget about the "score" and just put my 275 watt Globe King on the air - that guy burns a hole in the ether almost everywhere and I have fun talking to other AWA guys using it. Once more, I really think that dropping the power restrictions entirely would make for a better operating event.

3. The third problem other folks cited was unfavorable propagation. There's not a whole lot any of us can do about that. On Sunday afternoon when I was on for 40 minutes calling AWA, I heard quite a few signals on the air but just no other BK participants. Probably you guys were also on, the last hour on Sunday has been a good time to make a few contacts in past years. But the band was just not open between us.

So anyway, just my 2 cents worth. Thanks for all of your good discussion. Maybe we can make a few changes in the BK and also the LC which would up the participation and make for more good fun for all.

73,

Jim Hanlon, W8KGI, Sandia Park, New Mexico

I pushed 2 instead of 1 When mentioning Deforests patent date Feb18. Sorry.
I am going to go on then regardless. Feb 18 Deforests patent, seems as good a date as any.
Meanwhile I tried out the 6550 in the breadboard 80M rig.WOW!. TIme for a 600volt/6.3volt supply.
Reread the article Andy mentioned. My last two hartleys have much better notes then my first ones and my TNT is much improved since my first ventures. I thought the review would not hurt me. A little chirp I can live with but I want a good note. My Miltary rigs were all born with a distinctive chirp and they are staying as produced. The Collins is about 200 to 250cycles on the NJ SDR . Been working on a pond hop with it all week. I have a few days free of that now so time to play.

14829. Ross Hull test

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-23 14:27:59 UTC
From: aflowers@frontiernet.net
Topic: 14829 Message: 14829

Don and Group,
I did the "Ross Hull" test with one of my transmitters to plot the relationship between plate voltage and frequency. It's a little easier for us because we probably don't have to build a stable receiver to do this (he used an overbuilt "growler", resistance-coupled amplifier, and a tuning fork in an electrical oscillator). For accuracy you probably want a synthesized rig with dial readout to 10's of Hz. Then you need some way of adjusting the plate voltage (adjustable supply, variac, etc.).
Here's my method:
1) Transmit at the lowest plate voltage--say 100V and record this Wait for the signal to stabilize (thermal effects). You want the actual voltage during key down, not the unloaded, key-up voltage.2) Zero beat the signal with the receiver3) Record dial frequency4) Repeat at 1 with next highest plate voltage.
You could also just do this with a speaker and any piece of software that can give you an audio spectrum or any guitar tuning software that will read a tone out in Hz.
In the end you should have a table like this:
V | f400V 3562.50300V 3562.61200V 3562.72100V 3562.89
There's some error in this I'm sure, but in the end this one is pretty well adjusted in accordance with Ross Hulls findings--in fact, it should "only" take up about 500-600Hz (not including AM sidebands) if I were to run it with AC on the plate :-) The V/f slope is less with less coupling, but I start to loose more power as would be expected. In theory I should be able to adjust past maximum coupling to the antenna and operate on the *other side* of resonance, but my current arrangement won't physically allow that so I didn't try. Hull found that sometimes a transmitter behaves better over there, so it's something to investigate. If you have a series capacitor, that probably means turning it *past* maximum output so that antenna current starts to fall off again. You might even find the V/f curve is a little flatter there and the note is better.
This was done with a 203A obviously running at low plate voltage. This probably reduces thermal effects. When I get a chance I want to repeat this with a small tube like a 71A or 01A in the same circuit, but I need to come up with a jumbo tube base to make a jumbo-to-UX adapter.

Tnx for the mention. Lou.
There may not be too much interest in this type of activity.
I wonder if anyone would like to get an informal net going....
weekly, monthly or what ever. Just trying to think of some
way to get some regular on-air activity going.
Bill

Ok Don...
I know you operate around 3.6mc some...have you heard much
activity, primarily digital/rtty, say just under 3.6. Thinking about
staying away from the bottom of the fone band due to splatter, etc.
Maybe a few of us could squeeze between the digital and ssb QRM.
What abt 8PM EST time frame?
Bill

Yes I usually operate at 3562kcs with the breadboard rig. (more on that in a minute) It has been good but there is a net not far away. I know that because my friend VE3CDX is quite active in CW nets and that is how ewe met. I will check with Jim to find out exactly where they are so we stay clear. Say of they are in 3565 we could go to 3560. 8 pm is good. Wed and Sundays are not. I was just one with the breadboard rig there a few minutes ago. I built a supply from my junk box today for the new 6550 tube. Not as much HV as I would like but close to 500v. WOW! is all I can say. Tis a very impressive tube even at that voltage. It works so well in the 1940 ARRL breadboard transmitter I am not requiring a new rig. However I know, it tisnt what i would be using on the 29 net.

guitar tuning software

I have a tuner and it would do the job easily. good idea. I often watch the swing when tuning my violin (fiddle).
Normally I use my digital rx set in its finest step as the note changes rather abrubtly when the freq shifts a step which is to me too much.

Don
and Group,
I did
the "Ross Hull" test with one of my transmitters
to plot the relationship between plate voltage and
frequency. It's a little easier for us because we
probably don't have to build a stable receiver to do
this (he used an overbuilt "growler",
resistance-coupled amplifier, and a tuning fork in an
electrical oscillator). For accuracy you probably want a
synthesized rig with dial readout to 10's of Hz. Then
you need some way of adjusting the plate voltage (adjustable
supply, variac, etc.).
Here's
my method:
1)
Transmit at the lowest plate voltage--say 100V and record
this Wait for the signal to stabilize (thermal
effects). You want the actual voltage during key down, not
the unloaded, key-up voltage.2)
Zero beat the signal with the receiver3)
Record dial frequency4)
Repeat at 1 with next highest plate voltage.
You
could also just do this with a speaker and any piece of
software that can give you an audio spectrum or any guitar
tuning software that will read a tone out in Hz.
In
the end you should have a table like this:
V
| f400V

3562.50300V
3562.61200V
3562.72100V
3562.89
There's
some error in this I'm sure, but in the end this one is
pretty well adjusted in accordance with Ross Hulls
findings--in fact, it should "only" take up about
500-600Hz (not including AM sidebands) if I were to run it
with AC on the plate :-) The V/f slope is less with less
coupling, but I start to loose more power as would be
expected. In theory I should be able to adjust past maximum
coupling to the antenna and operate on the *other side* of
resonance, but my current arrangement won't physically
allow that so I didn't try. Hull found that sometimes
a transmitter behaves better over there, so it's
something to investigate. If you have a series capacitor,
that probably means turning it *past* maximum output so that
antenna current starts to fall off again. You might even
find the V/f curve is a little flatter there and the note is
better.
This
was done with a 203A obviously running at low plate
voltage. This probably reduces thermal effects. When I
get a chance I want to repeat this with a small tube like a
71A or 01A in the same circuit, but I need to come up with a
jumbo tube base to make a jumbo-to-UX adapter.

?Hello to John Dilks, K2TQN and everyone in the "AWA" Group,
?What's this about you not being able to climb towers anymore? I thought you promised to come over here and were to help me with the top section of my tower? I hope you're not going to go back on your word! I have a six element 6M "boomer" with a 34' mast that needs to be installed at the very top and thought you could handle the job - HI HI!

After the tower work I was going to "treat" for lunch and buy you a ham and cheese hoagie. I then need you to bring my Hallicrafters HT-9 from the garage to the basement shack. Do you mean to tell me you won't be able to handle the job? Am I to be dissapointed on both accounts?"

Geez, John. I thought you were up to handling both things I need to be done.Maybe I could ask Carl Nord, WA1KPD to come and help you with the HT-9. Maybe - HI HI!

Have a Happy Holiday anyway to you and everyone on the list.

I think this is on topic enough for the group... well, the first part anyway.

Last night I spent several hours listening for WI2XLQ (FCC Part 5 Experimental license) transmitting AM on 486 kHz with his UV-202 MOPA transmitter. The operation was to commemorate Reginald Fessenden's first audio broadcast 110 years ago. I don't mind telling you at nearly 800 miles a few watts of AM into a (probably) inefficient antenna on 486 kHz is a challenge. I could barely detect the music from time to time. Finally I managed to hear and understand the station ID "This is WI2XLQ..." (a couple of words I could not make out) "... on four hundred eighty six kilohertz". Whew! My ears hurt but mission accomplished!

I also listened for and heard Radio Grimeton / SAQ on 17.2 kHz using the 200 kW Alexanderson alternator. That may be a little off topic for this group... but what a thrill! This was the first time I had tried to hear it. I was using a $14 LF converter kit and my 80 meter inverted V with just the center conductor of the coax plugged in. It was nostalgic to hear hand sent Morse from a commercial station, not to mention use of the Morse colon character (twice).

I made recordings but only those with weak signal ears will admit there is anything but noise I'm sure. I thank my EME years (now way off topic) for preparing mine. :-)

Boy do I need a nap..... ZZzzzz.....

This is in particular for Don, VE3LYX, but everyone might enjoy it as well.

Don, since you are experiencing the wonders of a single 6550 oscillator, I thought you might be interested in a series of single 6L6 rigs presented in QST by Fred Sutter, W8QBW, from 1938 through 1940. They are, The QSL Forty, February 1938, page 24, with additions in March 1938, page 48 and July 1938, page 31, The Economy Forty, April 1939, page 18, the Runt 60 and QSL 60, September 1939, page 50, and finally the QSL Push-Pull, June 1940, page 26. The original QSL Forty ran from a 450 volt, 200 ma power supply, used a 6L6G, and delivered 40 watts output on 80 and 40 meters, and it's chassis was the size of a QSL card, hence the name. The last QSL Push Pull ran a pair of 6L6Gs and had an output of 100 watts. I don't know what the crystal current was in those rigs, but the older, pre-war rocks survived in those circuits.

If you don't have access to those articles let me know and I will send you copies.

73,

Jim, W8KGI

Thanks Jim, Some I have here. I use tall boy 6l6 tubes here. 6l6EH which are a big tube for a 6l6 (although small compared to a 6550) and have heard they can stand a lot of voltage as well. Although I think that at what is the upper limit for them a 6550 or KT88 would not even break a sweat. I remember reading though of a metal 6l6 upside down in motor oil running 1000 volts on the plate. I never wanted to push mine too hard. However the 6550 I think could probably handle 650 to 700 volts with ease. However I am surpprised at how the 6550 likes its new home. I am going to play with it for a bit with this PSU. Once I am comfy I may order a 650/6.3 volt transformer and see it I can hurt it. But I have heard of some of the performance folks got from 6l6 in years gone by and am amazed. Thanks for the reminders. I have most of 1940 QST here as well as the ARRL handbook. I will take a peak. donVe3LYX

I searched out the QSL 40 circuit. essentially the same circuit as my breadboard rig anyway. Probably also a fred Sutter design (1943 ARRL Handbook) but the writed/designer is not identified in the handbook. he does however mention you can run as much as 450 volts on the 6l6C plate and draw under full load s high as 80ma.
(50ma no load in resonance) So if you can do that with a 6l6C the 6550 can go a lot more it appears.
Speaking of big tubes. beam power ones specifically a friend came into batch of known good 813 pulls and wanted to know could I use one. I had jokingly one time mentioned an 813 final longfellow. so now I am thinking a 6550/813 long fellow. I have a ceramic 813 socket, a 813 parasitic suppressor /plate cap. Several ceramic door knob caps . A multi;ganged transmitting cap with wide spacing and a microwave oven transformer. If the 813 actually comes I think it will happen. I have started a parts box as I dig thru my stuff.

Attachments: 3 described; binary payloads are missing from this source WARC

All,

About a month ago I posted a description and some preliminary images of a superhet I was building using circuits, tubes, and other parts (mostly) that were around in the early-mid 1930s.

At this point, the set is complete except for a front panel, and I have wound coils that provide coverage of 160M, 80M, 40M, and 20M.

I am very happy with the way this set is working, and have been using it for nearly all my AM QSOs for the past few weeks. It also works on CW and SSB, of course, but the design's selectivity and tuning rate aren't optimized for those modes. (If there was room on the chassis for one more tube I'd add a cathode follower off the 1st IF xfmr to drive a 455 KHz Softrock!) Again, the tube lineup is 57 mixer, 56 local oscillator, 58 1st IF, 58 2nd IF, 2B7 2nd detector/AVC/1st audio, 56 phase inverter, pair of 59s PP class A audio output, 80 rectifier, 24A BFO using a dynatron circuit. It was a cool nostalgic project for this time of year. I hope to set it up in the shack for day-to-day use, but am having trouble deciding what to move out to make room for it - too much stuff, however I love it all!

I've include a few low-res photos; hi-res versions of these can be found here (for a while):

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_1.jpg

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_2.jpg

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_3.jpg

Between the the time I had sent out the fist images and these, I lost the original power transformer - it developed a short in one of the windings - so I replaced it with one that was functionally equivalent. The replacement takes up less space on the chassis, and a piece of aluminum sheet was used to cover up the rest of the hole that was there to accommodate the original transformer.

I am still seeking the escutcheon that matches the #1284 Pilot drum dial (see previous posts).

73, and I hope you found this post interesting.

-Larry/NE1S

Excellent job Larry. Not too many can claim that they are using a home brew receiver of this caliber in this modern age. I wish I would have kept the HBR-16 that I built prior to leaving for college in ‘65. Hope you and the family had a great Christmas along with everyone else on here. 73 – Mike

All,

About a month ago I posted a description and some preliminary images of a superhet I was building using circuits, tubes, and other parts (mostly) that were around in the early-mid 1930s.

At this point, the set is complete except for a front panel, and I have wound coils that provide coverage of 160M, 80M, 40M, and 20M.

I am very happy with the way this set is working, and have been using it for nearly all my AM QSOs for the past few weeks. It also works on CW and SSB, of course, but the design's selectivity and tuning rate aren't optimized for those modes. (If there was room on the chassis for one more tube I'd add a cathode follower off the 1st IF xfmr to drive a 455 KHz Softrock!) Again, the tube lineup is 57 mixer, 56 local oscillator, 58 1st IF, 58 2nd IF, 2B7 2nd detector/AVC/1st audio, 56 phase inverter, pair of 59s PP class A audio output, 80 rectifier, 24A BFO using a dynatron circuit. It was a cool nostalgic project for this time of year. I hope to set it up in the shack for day-to-day use, but am having trouble deciding what to move out to make room for it - too much stuff, however I love it all!

I've include a few low-res photos; hi-res versions of these can be found here (for a while):

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_1.jpg

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_2.jpg

https://dl.dropboxusercontent.com/u/69963783/NE1S_hbrew_super_3.jpg

Between the the time I had sent out the fist images and these, I lost the original power transformer - it developed a short in one of the windings - so I replaced it with one that was functionally equivalent. The replacement takes up less space on the chassis, and a piece of aluminum sheet was used to cover up the rest of the hole that was there to accommodate the original transformer.

I am still seeking the escutcheon that matches the #1284 Pilot drum dial (see previous posts).

73, and I hope you found this post interesting.

Thanks, Mike. FB on the HBR-16. I had built a couple of superhets when I was in high school, but none before now deserving the description of "communications receiver."

We did have a good Christmas; my brother's family was here, as well as one of our three boys - the one that still lives close enough to come visit occasionally. But I stayed up well past my bedtime - my son is a night nurse so he is on a different schedule. I didn't get to bed until after midnight. I can't remember the last time I stayed up that late, or the last time I slept until 8AM, which I did this morning!*
*
I also hope you and everyone else on here had a great Christmas, or whatever holiday each celebrates.*
*
CU on the AWA topband net tonight (all are welcome: 1945 KHz LSB 8PM Eastern).

73,
-Larry/NE1S*

Hello Larry, Just google "Ross Hull Superhet". There are some beautiful copies of that receiver. I guess the original article is March 29, QST. I see that your receiver may be a few years later, but a very fine example of an early superhet! 73 Jim kk4gfr

And I have a 600 volt supply but it is a dedidicated supply for my no 19 WS. And it has 12 v DC heater supply.
I just rebuilt it a week ago to see if I could get rid of the hum. I did. So I just run the 6550 on its current supply. Power out is very good.
I just had a 813 donated to the cause. I found my 813 ceramic socket and my doorknob caps. A huge coil form and a NOS microwave transformer. Maybe a 6550/813 long fellow. Gonna need bigger wooden slats.
Spent the morning working on the TCS Collins station. Was on 80M AM for a bit with good reports. Fixing the RX was brutal. Still needs a bit but works pretty good. Never had it on 160M yet as a station. Takes a while to figure out the tune and log it on the tune sheet. Will be listening tonight though while I am working.
Nice Superhets , both of U.

14864. AWA '29er Net Procedures

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-27 19:13:37 UTC
From: Bill Stewart
Topic: 14864 Message: 14864

Good Afternoon All,
Here is a simple procedure that maybe we can follow for the net...
just to keep things from getting jumbled up.There are now Q-signals
for net use if anyone wants them to be used. I have been over this in
numerous 'faux' net sessions and seems to be pretty smooth. Everyone
please go over this and see how it works for you. I expect we will be
passing the NCS duties around some. This is just a rough draft and I'm
sure every situation is not covered....so wing it...we are all among friends.
Any comments, changes, etc will be most welcome.
73 de Bill K4JYS

Net Control Station Procedure (NCS....in bold):

First make call to see if freq. is busy
QRL? pause and listen QRL? pause and listen
If clear call up Net

CQ AWA CQ AWA 29er Net de N4NCS NCS
CQ AWA CQ AWA 29er Net de N4NCS NCS
All stations are welcome BT
Check ins please (or Ck Ins Pse) K

Stations check in and NCS keeps list, in order of check in
(Acknowledge check ins)
VE3--- W1--- KB1--- .....WB3 --- de N4NCS Pse QRX
CQ AWA CQ AWA 29er Net de N4NCS NCS
Check ins please (or Ck Ins Pse) K

Any QSP? (relay) K
Any station can relay a check in not heard by NCS
Pick up & acknowledge relayed check ins...if none, go ahead with net

AWA 29er Net de N4NCS NCS BT
GE all and tnx for cking in, welcome...with a few short comments, stn info, etc
BT
Here is the order VE3--- to W1--- to KB1---to........to WB3.... (last stn in
the order turns it back to NCS)
(order of transmissions same as check in order)
BT
Go ahead (Call or Name if known) Joe and start it off (...or something similar)
VE3--- de N4NCS K
Stations comments: please include your sig rpts, station info, etc
Last station in the order return it to NCS

WB3--- (last station in order) de N4NCS
R Pse QRX
After each complete round, make a call for additional check ins

AWA 29er Net de N4NCS NCS
Other ck ins pse K

Any QSP? (relay) K

Add any additional ck ins to end of order
Make additional rounds for comments as needed, with a net call after each complete round

Ending net
AWA 29er Net de N4NCS NCS
Thanks for your ck ins (73, etc with final comments from NCS)
SK
THE AWA 29er Net is now closed de N4NCS CL

NOTE: NCS be sure to listen for the western stations and for QSPs from stations. Might be a good idea to ask a MN, WI, IL, etc station to make a net call in case there is a station from the west trying to check in. Also NCS and all stations should always tune off net freq for off-freq stations.

Looks good. He (Mich Net guy) does not reply to QRL or CQ. Just pops his carrier on for a second randomly or sends T E S T but sends it like NST. I have learned that if I sign QRT he jumps in and goes. I would not purposely stand in his way though so if he gave me a hinweiss it would sure help. If he replied or answered I would be out of his hair and gone but I guess he doesn't know that.

Don,

The RCA ad on the back cover of QST for March, 1939 features a circuit using the 813 as a Reinartz tetrode crystal oscillator, along with all of the component descriptions. They use a 1500 volt power supply and 80 and 40 meter crystals. They claim 150 watts output in CW service and 100 watts carrier output with 60% efficiency in AM phone service, 100% modulated.

Just a thought,

Jim, W8KGI

Well, its worth a shot. I must have missed your intended day of week somewhere. I'm just getting home from work during the week around this time anyway so I would be a late checkin :-)

Hope you can get a good amount of participation for this net. Probably if there are fewer than six on you could just go to an informal roundtable like the old glowbugs group. I've been eyeballing my 80 m 1929 MOPA (twin 27 Hartley to 865 amp) trying to figure out where I can fit it in !

Works for me! I may have that issue. i will check. Interesting today I did some tests with the 6l6eh against the 6550. The 6l6eh has no trouble with the voltage I am currently using and keys well and sounded good on the monitor but power out is around 60% of with the 6550 if meters in shack are to be believed. Tuning between the two tubes is quite different because I believe of the difference in the tube's natural C. Anyway god my parts out on the corner of the bench . Gotta figure out the microwave transformers winding. Probably will feed them with a 6.3 v transformer and do the math.

Guess we might as well pick a night and freq.
At the moment, Wed and Sun nights are out. And am thinking that Sat might have QRM from some type of contest...which may not be so if we go around 3.6....so maybe we can pick
Mon, Tue, Thur, Fri, (Sat?)....any preferences?

As for freq....around 3562 had a weak net start up at 8PM. Lou, you are right, not much going on (from 8 to now...around 8:45PM) from around 3598 to well above 3610. I am basing this on reception from a Web SDR rx in NJ. Can anyone else give activity reports for this freq range? Do ya think we oughta hang close to 3.6....
Wat sa on this Lou? Pick the sweet spot.

OK, how's this? 8PM Tuesday on 3615kc. If QRM, NC QSYs down.

Now, what is the official WPM of the net? For OM Cro's benefit, under 80.

The time....8-9PM EST has been the time sorta zeroed in on,
during the discussion, but guess there's no big reason not to
move it up a tad. I haven't done any freq cking after 9PM.
How abt a compromise at 8:30PM EST and we can see if
the western guys can make it in around 9PM or so. We can
make adjustments as we get experience.

Comments anyone?
Bill

Hello Bill!

I've been on the Bruce Kelley QSO Party, and the others since 2009, but I'm rather new to this list, so I've been reading a while before commenting, ha!

Thanks for getting this going! I think it's great -

Later in the evening, on a weeknight, sounds good to me. 8 PM or later, Monday or Thursday?

The only thing about 3600 or above, is that rules out those of us who are not Extra Class Hams.

I'm an old Advanced, and reluctant to give that up - I'm been thinking about it for 20 years or so...

Jim VE3DCX and I were retesting my 6550 tubed TX and working around his schedule as he had family visits to make. As per usual I did the top of each hour thing starting at 6 PM . on 3564 signals were the best we have ever had between us. Normally I would not be on then. CHU was strong and clear . Didn't think to check WWV . Absolutely no QRM. Another possibility (perhaps) is mornings 80M is always good. I often do 80M AM ops before 830 AM and have for a few years. By 9 it starts to crap out. Coffee and code is always a good combo.
Just for fun last night I whipped up an external BFO on the Collins first If like Jim taught me. It could not work better. Figuring out know how to cable it for switching . May use the original in dead stick mode for an audio filter of sorts. I could read SSB signals so well I could not be sure if they were SSB or AM.

GM All,
First here is a list of all interested parties as of this morning:
WA6VYN AB0CW KK4GFR W1ZB VE3LYX VE3AWA
KB0ROB WB9WHG WT2W K4JYS
Excellent....

It's hard to get the scheduled time and freq to suit all, but this is
a flexible net and we can adjust as we go along if necessary. It
looks like we will need to move below 3.6mc to accommodate
all license classes...something I didn't think about. Lets take
another look around 3562 up for a clear spot between 8:30 and
9:30 PM EST...and we can stay around later if no net fires up.
Looks like the 2nd Tues night of the month will fit most ops...
so, if ok, we will shoot for Jan 10 and in the future the second Tues
of each month....starting at 8:30PM EST ....freq. will be announced
in a few days.

Can't remember who it was that had access to the list of net freqs,
but could you take a look and see whats going on net-wise from
around 3562 up to where the digital modes start.....tnx.

A NCS is also needed....any volunteers?

That's the latest...73 de Bill K4JYS

14902. de K1TG - Part needed

Yahoo group: AWAGroup (2014 — 2016)
Date: 2016-12-29 17:06:36 UTC
From: Roger Kuchera
Topic: 14902 Message: 14902

GA Gentlemen, Once again I find my junque box is lacking a critical part I need for a restoration. To wit:

One (1) - 6-pin coil form, Phenolic. a ribbed form of 2 1/4 inches diameter (Large type). If memory serves me both Bud and Hammarlund made them. New or Used is fine as long as a used one doesn't resemble a Swiss cheese.

I will trade or buy such a unit. I have a fairly large selection of coil forms made by Bud,Hammarlund, ICA, Octocoil.

As always the help is most appreciated. Thanks!

Roger/K1TG

Sent: Thursday, December 29, 2016 11:59 AM
To: boatanchors@...
Subject: Re: [Boatanchors] "Chirp is a Beautiful Thing"

Hi,

Some of the old timers like to howl and carry on about how they used to walk 10 miles to school through chest deep snow uphill both ways. And how they could so easily pick out one transmitter from the many that could be heard simultaneously on a novice band. Those transmitters all had their own, individual voices and combining that with all those individual fists - of course it was easy. At least less difficult. Some amount of chirp is one of the ingredients. The accursed 'yaecomwood' radios are pretty much "sterile" and all sound alike. CW is sent by keyers, memory keyers, and computers. Pretty much sterile, too.

I have looked at some signals with varying amounts of chirp on waterfall displays and I see a small "j" hook on the leading edge. It doesn't take much. There is no need to sweep a dit or dah across two or three QSOs in progress but a small dose of chirp goes a long way toward individual identification. Put the same amount of 'hook' on the other side and two otherwise identical stations are *different*. I have heard some signals in the past that I know must be from a small amount of modulation - perhaps FM - on that CW tone. It wasn't enough to identify the source of the "problem" but it was enough to identify one ham and his station - instantly. Operating as NCS in NTS traffic nets I could recognize and acknowledge certain stations from just one character in Morse. It isn't all bad.

73,

Bill KU8H

Removing oxidation from hardrubber stator supports.
600 grit wet & dry with water.

Need Kurz-Kasch 3" dial.
Considering the project, condition is secondary. No chips or cracks would be a help tho.
Ideally the scale would read 100-0, but 0-100 would do.
One shown has another job to do.
Thanks, Lou

Interesting timing - I'm looking for the same part only in a 1.5" form - four total.
I'm wondering if anyone is using a 3D printer to manufacture parts being difficult to find or unavailable.
Or was that a blasphemous question? Hi

Peter N0GRM

  Removing oxidation from hardrubber stator supports.600 grit wet & dry with water. Need Kurz-Kasch 3" dial.Considering the project, condition is secondary. No chips or cracks would be a help tho.Ideally the scale would read 100-0, but 0-100 would do. One shown has another job to do. Thanks, Lou

1936 Superhet receiver - Starting with an ARRL design (book and Feb 36 article). Oscillator and Mixer coils.
I wound the 80m oscillator on 1.5" pvc sink pipe - and built the osc circuit around that - it works fine - 6D6 tube.

Six pins -

And it was the April 1936 issue of ARRL where the follow up article and schematic to that found in the handbook.

Thanks

Hi Roger,

Does what your looking for have a hole drilled through it?

Do u mean thru the knob? Is so, no.

Lou

Thank you, Peter.

There has been an avalanche of sophisticated RX this season. Wonderful. I'm sure that you will be taking photos from all angles when completed. Please post them here or in a Group File.

Larry, Roger, you too please.

Lou
